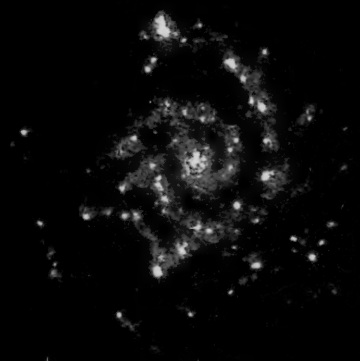
Scientific and Technical Aerospace Reports



An Abstract Journal

Volume 32, Number 9
September 1994
N94-30981 to N94-33356

The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

NASA Access Help Desk

Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON, and through DIALOG as the Aerospace Database.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **3565**

02 AERODYNAMICS **3567**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **3574**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **3576**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **3578**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **3581**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **3583**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **3585**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **3586**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **3591**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **3601**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **3602**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **3602**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **3608**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMANDAND TRACKING....N.A.
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **3609**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **3613**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **3613**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **3616**

24 COMPOSITE MATERIALS **3617**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **3631**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **3640**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **3648**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **3666**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **3667**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **3668**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **3670**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **3686**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **3699**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **3711**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **3714**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **3722**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **3730**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **3732**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **3741**

43 EARTH RESOURCES AND REMOTE SENSING **3741**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **3758**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **3763**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **3770**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **3776**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **3787**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **3792**

52 AEROSPACE MEDICINE **3794**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **3798**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **3802**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY **3806**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **3806**

60 COMPUTER OPERATIONS AND HARDWARE **3806**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **3808**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **3823**
Includes computer networks and special application computer systems.

63 CYBERNETICS **3828**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **3839**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **3850**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **3852**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **3855**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **3858**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **3859**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **3862**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **3875**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **3877**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **3885**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **3894**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **3910**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **3913**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **3914**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **3915**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **3924**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY **3924**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **3924**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) ..... **N.A.**

89 ASTRONOMY **3924**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **3927**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **3939**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **3952**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **3954**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

AN ANALYSIS OF THE MAINTENANCE PERFORMANCE MEASUREMENT SYSTEM FOR LAMPS MK 3 HELICOPTER SQUADRONS M.S. Thesis
Richard K. Fawcett Dec. 1993 212 p
(AD-A276421) Avail: CASI HC A10/MF A03

With the current downsizing of the United States military and the defense budget, the diminishing availability of resources has increased the focus on the need for effective management. This thesis discusses several factors affecting performance improvement (effectiveness, efficiency, quality, productivity, budgetability, quality of work life, and innovation) for LAMPS MK 3 helicopter squadrons. Current non-financial measures for monitoring the performance of maintenance are examined and evaluated. Alternative maintenance performance measures are described and discussed. The alternative measures for which source data is available are analyzed. A new performance measurement model, the Multi-Criteria Performance/Productivity Measurement Technique, and the Objectives Matrix, is described and recommended for measuring LAMPS MK 3 helicopter squadron maintenance performance. AN EVALUATION OF AIRCRAFT MAINTENANCE PERFORMANCE FACTORS IN THE OBJECTIVE WING M.S. Thesis
Mark A. Gray and Margaret M. Ranalli Sep. 1993 152 p
(AD-A276010; AFIT/GLM/LA/93S-22) Avail: CASI HC A08/MF A02

Prior to 1992, organizational maintenance was aligned under a separate maintenance organization. In 1992, the Air Force restructured into objective wings with organizational maintenance aligned under the flying squadrons. This study looks at the impact of this reorganization on maintenance performance factors. The researchers developed maintenance performance models using regression and principal component analysis. Mission capable rate and total not mission capable maintenance rate are used as dependent variables. A comparison of key maintenance performance indicators and model predictions before and after the reorganization is accomplished. Based on the results of this analysis, the researchers conclude that there is significant improvement in all dependent variables, model predictions of these dependent variables, and some of the independent variables. Improvement occurred after organizational structure changed; however, other factors not included in the models such as the stand-down of the alert force may also contribute to this improvement. DTIC

INITIAL ESTIMATES OF INTEGRATED MAINTENANCE INFORMATION SYSTEM (IMIS) COSTS AND BENEFITS, VOLUME 1 Final Report, Jul. - Sep. 1993
Robert J. Tomasetti, A. B. Calogero, Charlie E. Jones, Charles L. Hanna, and Thomas J. Guarino Oct. 1993 53 p
(Contract F33600-85-D-7002)
(AD-A276144; AL/HR-TR-1993-0178-Vol-1) Avail: CASI HC A04/MF A01

This report analyzes the system-wide costs and benefits of implementing the Integrated Maintenance Information System (IMIS) for the F-16. The Human Resources Directorate of the Armstrong Laboratory has undertaken IMIS as an Advanced Technology Transition Demonstration (ATTD) effort. ATTD efforts provide proof-of-principle demonstrations conducted at the system or major subsystem level in an operational environment. They demonstrate the potential of new technologies to provide significant improvements in cost-effectiveness. IMIS has the potential to provide major improvements in the efficiency of aircraft maintenance processes. This report documents the initial effort to develop a rough order of magnitude estimate of the functional costs and benefits of implementing the IMIS technology. Estimates are developed for the Base Case and two IMIS implementation alternatives. The alternatives are analyzed, results identified, and conclusions reached. DTIC

PROSPECTS FOR THE FRENCH FIGHTER INDUSTRY IN A POST-COLD WAR ENVIRONMENT: IS THE FUTURE MORE THAN A MIRAGE? Ph.D. Thesis
Yolande Marie Simon 1993 344 p
Avail: Univ. Microfilms Order No. DA9327555

Since withdrawing from NATO's integrated military structure in 1966, France has striven for self-sufficiency in the defense sector. A major component of this policy has been to maintain an independent arms

manufacturing capability, particularly a fighter industry. The small size of the domestic market has necessitated an aggressive export policy, which met with considerable success under the guidance of French aviation industrialist Marcel Dassault. France found a niche in marketing midrange, moderately priced fighters (the Mirage series) known for their simplicity, reliability, and excellent performance. This strategy was altered in the early 1980s with the design of the Rafale multirole fighter, which will directly compete with American or Soviet fighters. This new strategy comes at a time when a variety of factors have been threatening France's arms export policy: shrinking international arms market, increasing cost of weapons, and intensified competition. The collapse of the Soviet Union, compounded with economic recession, has led to the slowing or elimination of aircraft modernization programs. In this changing environment, is the concept of an independent French fighter industry more than a mirage? This report sheds new light on the prospects for the French fighter industry. It seeks to estimate the potential export sales of the Rafale over the next twenty years, to offer an independent estimate of the cost of the Rafale program and to compare it with published cost estimates, and to explore the viability of the Rafale program in light of these two estimates. To these ends, this paper considers both the demand for and the cost of the Rafale. Part 1 describes the inception of the Rafale program, the controversies which have surrounded it, and those aircraft which will compete most directly with it. Part 2 probes the potential global demand for fighters over the next two decades and estimates the future demand for French fighters. Part 3 analyzes the cost of the Rafale, using DAPCA, a cost analysis model created at RAND. Finally, this paper considers the implications of these assessments for the future of the Rafale program and the French fighter industry. Dissert. Abstr.

N94-32157# Federal Aviation Administration, Atlantic City, NJ. Technical Center.

SHEAROGRAPHIC INSPECTION OF A DEHAVILLAND DHC-7

Stephen N. Bobo Dec. 1993 24 p

(AD-A276716; DOT/FAA/CT-TN92/39) Avail: CASI HC A03/MF A01

Under a Cooperative Research and Development Agreement between the Volpe National Transportation Systems Center (VNTSC) and Henson Aviation, Inc., operator of USAir Express, a shearographic demonstration inspection of the fuselage of a DeHavilland DHC-7 aircraft was performed at a US Air repair station at Norfolk, VA, on August 8, 1992. The inspection compared the effectiveness of shearography with currently mandated methods in detecting disbonds in the fuselage. Adhesive bonding is utilized in modern aircraft fuselages, frequently in combination with rivets. As aircraft age, bond failure becomes a major problem, since it may promote fatigue cracking, moisture intrusion, and subsequent corrosion. Any of these events may cause cabin pressure loss and, sometimes, catastrophic fuselage failure. The shearographic method of detecting disbonds depends on the deformation of the aircraft skin under mechanical stimulus. When illuminated by coherent light, the phase relationship and intensity of the light reflected from any two points of the skin changes as a result of this deformation. Surface changes down to 0.00025 millimeter can be detected and displayed as a real-time image of the field of view. Comparison of successive images as the deformation changes permits interpretation of the condition of a bond. In addition, other selected areas of the aircraft suspected to contain disbonds were inspected. No disbonds were found either by shearography or confirming ultrasound readings. Shearography was clearly able to identify the presence of waffle doublers wherever drawings of the aircraft indicated that they should exist. DTIC

HUMAN COMPUTER INTERFACE SPECIFICATIONS (HCIS) FOR THE INTEGRATED MAINTENANCE INFORMATION SYSTEM (IMIS)

Jeffrey L. Wampler, David R. Gunning, Cher E. Wynkoop, Laurie L. Quill, and Laura L. Moorman Oct. 1993 145 p

(Contract F33615-88-C-0024)

(AD-A277184; AL/HR-TP-1993-0035) Avail: CASI HC A07/MF A02

The Armstrong Laboratory Logistics Research Division (AL/HRG) is developing a proof-of-concept Integrated Maintenance Information System (IMIS). The IMIS will demonstrate the capability to access and integrate maintenance information from multiple sources and present the information to technicians and maintenance personnel through hand-held and workstation computers. A significant part of IMIS is the user interface. Current practices in the DoD procurement process do not emphasize the specification of a system's user interface as requirements. Instead, the user interface is often designed as the system develops. This paper documents a baseline user interface specification for all IMIS applications and a detailed user interface specification for an interactive electronic technical manual (IETM) presentation system. AIRBORNE TRAILBLAZER: TWO DECADES WITH NASA LANGLEY'S 737 FLYING LABORATORY

Lane E. Wallace 1994 193 p *Its* NASA History series Original contains color illustrations

(NASA-SP-4216; NAS 1.21:4216; LC-94-5874) Avail: CASI HC A09/MF A03; SOD HC; 76 functional color pages

This book is the story of a very unique aircraft and the contributions it has made to the air transportation industry. NASA's Boeing 737-100 Transport Systems Research Vehicle started life as the prototype for Boeing's 737 series of aircraft. The airplane was acquired by LaRC in 1974 to conduct research into advanced transport aircraft technologies. In the twenty years that followed, the airplane participated in more than twenty different research projects, evolving from a research tool for a specific NASA program into a national airborne research facility. It played a critical role in developing and gaining acceptance for numerous significant transport technologies including 'glass cockpits,' airborne windshear detection systems, data links for air traffic control communications, the microwave landing system, and the satellite-based global positioning system (GPS). FAA AVIATION FORECASTS, FISCAL YEARS 1994-2005

Mar. 1994 194 p

(AD-A277808; FAA-APR-94-1) Avail: CASI HC A09/MF A03

This report contains the Fiscal Years 1994-2005 Federal Aviation Administration (FAA) forecasts of aviation activity at FAA facilities. These include airports with FAA control towers, air route traffic control centers, and flight service stations. Detailed forecasts were made for the major users of the National Aviation System: air carriers, air taxi/commuters, military, and general aviation. The forecasts have been prepared to meet the budget and planning needs of the constituent units of the FAA and to provide information that can be used by state and local authorities, the aviation industry, and the general public. The slow pace of the economic recovery in United States and economic recessions in several of the major world trade areas have caused the aviation industry to experience continued slow traffic growth. However, the outlook for the 12-year forecast period is for moderate economic growth, stable real fuel prices, and modest inflation. Based on these assumptions, aviation activity for fiscal year 2005 is forecast to increase by 22.6 percent at towered airports and 24.0 percent at air route traffic control centers. The general aviation active fleet is forecast to decline by 3.8 percent during the forecast period but increased utilization (hours flown by aircraft) results in a 12.0 percent increase in general aviation hours flown during the same period. Scheduled domestic revenue passenger miles (RPM's) are forecast to increase 55 percent, scheduled international RPMS are forecast to increase by 108 percent, and regional/commuter RPM's are forecast to increase by 166 percent. This report selectively summarizes the NASA Lewis Research Center's research and technology accomplishments for the fiscal year 1993. It comprises approximately 200 short articles submitted by the staff members of the technical directorates. The report is organized into seven major sections: Aeronautics, Aerospace Technology, Space Flight Systems, Space Station, Engineering and Computational Support, Lewis Research Academy, and Technology Transfer and Utilization. A table of contents by subject has been developed to assist the reader in finding articles of special interest. This report is not intended to be a comprehensive summary of all research and technology work done over the past fiscal year. Most of the work is reported in Lewis-published technical reports, journal articles, and presentations prepared by Lewis staff members or by contractors. In addition, university grants have enabled faculty members and graduate students to engage in sponsored research that is reported at technical meetings or in journal articles. For each article in this report a Lewis contact person has been identified, and where possible, reference documents are listed so that additional information can be easily obtained. The diversity of topics attests to the breadth of research and technology being pursued and to the skill mix of the staff that makes it possible. Author

A fundamental advantage for performing material processing and fluid physics experiments in an orbital environment is the reduction in gravity driven phenomena. However, experience with manned spacecraft such as the Space Transportation System (STS) has demonstrated a dynamic acceleration environment far from being characterized as a 'microgravity' platform. Vibrations and transient disturbances from crew motions, thruster firings, rotating machinery etc. can have detrimental effects on many proposed microgravity science experiments. These same disturbances are also to be expected on the future space station. The Microgravity Science and Applications Division (MSAD) of the Office of Life and Microgravity Sciences and Applications (OLMSA), NASA Headquarters recognized the need for addressing this fundamental issue. As a result an Advanced Technology Development (ATD) project was initiated in the area of Vibration Isolation Technology (VIT) to develop methodologies for meeting future microgravity science needs. The objective of the Vibration Isolation Technology ATD project was to provide technology for the isolation of microgravity science experiments by developing methods to maintain a predictable, well defined, well characterized, and reproducible low-gravity environment, consistent with the needs of the microgravity science community. Included implicitly in this objective was the goal of advising the science community and hardware developers of the fundamental need to address the importance of maintaining, and how to maintain, a microgravity environment. This document will summarize the accomplishments of the VIT ATD which is now completed. There were three specific thrusts involved in the ATD effort. An analytical effort was performed at the Marshall Space Flight Center to define the sensitivity of selected experiments to residual and dynamic accelerations. This effort was redirected about half way through the ATD focusing specifically on the sensitivity of protein crystals to a realistic orbital environment. The other two thrusts of the ATD were performed at the Lewis Research Center. The first was to develop technology in the area of reactionless mechanisms and robotics to support the eventual development of robotics for servicing microgravity science experiments. This activity was completed in 1990. The second was to develop vibration isolation and damping technology providing protection for sensitive science experiments. In conjunction with the this activity, two workshops were held. The results of these were summarized and are included in this report. Author

CFD-BASED DRAG PREDICTION: STATE-OF-THE-ART, THEORY, PROSPECTS
J. vanderVooren and J. W. Slooff 15 Sep. 1992 75 p Presented at the AIAA Professional Studies Series, Course on Drag-Prediction and Measurement, Portland, OR, 23-24 Aug. 1990 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B179297; NLR-TP-90247-U; ETN-94-95974) Avail: CASI HC A04

An overview of the state of the art and the theory of Computational Fluid Dynamics (CFD) based drag prediction, with some emphasis on transport aircraft, is presented. The entire field, ranging from potential codes to Reynolds averaged Navier-Stokes codes is covered. Only steady flow, in the absence of propulsion, is discussed. It is concluded that, although CFD based drag prediction can be viewed with 'cautious optimism', it still has a long way to go; research and development in CFD post processing routines for drag prediction purposes is required for many years to come. AN ADAPTIVE FINITE ELEMENT METHOD FOR UNSTEADY COMPRESSIBLE ROTOR AIRFOIL AERODYNAMICS Ph.D. Thesis
Bruce Eugene Webster 1993 199 p
Avail: Univ. Microfilms Order No. DA9325276

The accurate treatment of unsteady compressible rotor airfoil aerodynamic flows requires the capability to efficiently resolve the widely varying length scales of the flow physics as they evolve temporally. An adaptive finite element methodology suitable for this type of problem is developed in this thesis. It is based upon an automated adaptive environment consisting of the Finite Quadtree automatic mesh generator, a time-discontinuous Galerkin Least Squares finite element flow solver, an error indicator based upon interpolation estimates, and a mesh enrichment procedure. The time-discontinuous Galerkin Least Squares finite element flow solver is particularly well suited to handle problems with multiple relative motion. A linear space-time wedge element formulation was developed and implemented which is suitable for two dimensional problems with relative body motion. The mesh enrichment procedure developed to enable the solution process to be spatially adaptive (h-refinement) is edge based and stores no mesh enrichment history. Steady and unsteady transonic airfoil calculations show good correlation with other experimental and numerical data. Based upon these results it is concluded that this type of automated adaptive CFD technique is a viable computational tool capable of accurately resolving unsteady compressible flow features and should be developed further to handle three dimensional problems where multiple relative motion is important, i.e. the flow field around an entire helicopter. CONTROL OF HYPERSONIC AERODYNAMIC FORCES WITH SURFACE

BLOWING Ph.D. Thesis
Michael David Matarrese 1993 156 p
Avail: Univ. Microfilms Order No. DA9319582

Aerodynamic forces are obtained for laminar flow past a slender wedge at high Mach number and high Reynolds number, with a cool inert gas injected at the surface. Mass-flow rates are taken to be large enough to blow the boundary layer away from the wall as a free shear layer, but small enough that the effective body remains thin. Cases studied include distributed blowing where the wall mass flux is proportional to a power of the streamwise coordinate, uniform blowing from a strip located downstream from the wedge vertex, and various examples of time-dependent mass injection. For power-law blowing, self-similar solutions are obtained in the strong- and weak-interaction limits for the layer of blown gas adjacent to the surface, for the viscous shear layer, and for the outer inviscid-flow region between the shear layer and the shock wave. Formulas are derived which relate the surface pressure and surface shear stress to the mass flow, and the behavior of the pressure force and drag are examined for a range of parameter values, for different injectants, and for various distributions of the injected mass. Equilibrium dissociation of oxygen and other real-gas effects are included in part of the analysis. For strip blowing on a cool wall, mass flows are chosen such that the flow separates upstream of the slot leading edge in a hypersonic free interaction. The pressure force as a function of mass-flow rate is obtained for various slot geometries, including an example with two slots. For unsteady distributed blowing, time histories of the pressure force are computed for various cases where the shear layer may be neglected and the time rate of change of the wall boundary conditions is small compared to the residence time in the outer flow. Dissert. Abstr.

PREDICTION OF TRANSONIC POTENTIAL FLOW WITH SLIPSTREAMS AROUND CONFIGURATIONS
Wang Dieqian and Sven G. Hedman Feb. 1993 58 p Sponsored by Aeronautical Research Inst. of Sweden
(Contract NUTEK-5623-92-01540)
(FFA-TN-1992-15; ETN-94-95879) Avail: CASI HC A04/MF A01

A potential flow code was developed for the simulation of transonic flow around wing/body/nacelle configurations and for the prediction of propeller/airframe interference. The propeller is modeled as an actuator disk, and the effect of the slipstream is considered in an approximate way. The wing/body/nacelle flow solver and the grid generator were developed from earlier codes for wing/body cases. The computational space is divided into two blocks, with one block inboard and one outboard of the nacelle. The algorithm for the two block case is fully implicit not only in all the three coordinate directions but also between the two blocks. It is uniformly stable for all regions in the field. The method uses almost the same CPU (Central Processing Unit) time as the one block solver does for wing/body configurations. Hence, it is a very robust algorithm and the method is cost effective. Applications are shown for three cases simulating propeller driven airplanes in subsonic climb and transonic cruise. Comparisons are made with data from Euler code calculations and also with results from wind tunnel tests. In general the obtained agreement is very good. ESA

GRID SENSITIVITY FOR AERODYNAMIC OPTIMIZATION AND FLOW ANALYSIS Ph.D. Thesis
Ideen Sadrehaghighi 1993 119 p
Avail: Univ. Microfilms Order No. DA9319038

An algorithm is developed to obtain the grid sensitivity with respect to design parameters for aerodynamic optimization. Two distinct parameterization procedures are developed for investigating the grid sensitivity with respect to design parameters of a wing section as an example. The first procedure is based on traditional (physical) relations defining NACA four-digit wing sections. The second is advocating a novel (geometrical) parameterization using spline functions such as NURBS (nonuniform rational b-splines) for defining the wing section geometry. An interactive algebraic grid generation technique, known as two-boundary grid generation (TBGG), is employed to generate C-type grids around wing sections. The grid sensitivity of the domain with respect to design and grid parameters has been obtained by direct differentiation of the grid equations. A hybrid approach is proposed for more geometrically complex configurations. A comparison of the sensitivity coefficients with those obtained using a finite difference approach is made to verify the feasibility of the approach. The aerodynamic sensitivity coefficients are obtained using the compressible, two dimensional, thin-layer Navier-Stokes equations. An optimization package has been introduced into the algorithm in order to optimize the wing section surface using both physical and geometric parameterization. Results demonstrate a substantially improved design, particularly in the geometric parameterization case. Dissert. Abstr.

EXPERIMENTAL AND NUMERICAL SIMULATION OF HELICOPTER ROTOR FUSELAGE INTERACTION Ph.D. Thesis - Aix-Marseille Univ. [SIMULATION EXPERIMENTALE ET NUMERIQUE DE L'INTERACTION ROTOR-FUSELAGE D'HELICOPTERE]
Roland Hanotel 1993 141 p In FRENCH Original contains color illustrations
(ISSN 0078-3781)
(ONERA-NT-1993-8; ETN-94-96063) Avail: CASI HC A07/MF A02

A Computational Fluid Dynamics (CFD) method for prediction of helicopter/fuselage interactions is proposed. The main rotor blades are modeled using lifting line theory, with the rotor wake discretized using a lattice of radial and tangential elements. The fuselage is modeled by a surface distribution of sources and doublets. The interaction is computed by balancing out iteratively the influence of the rotor and that of the fuselage. The latter was analyzed by means of isolated rotor and coupled fuselage/rotor computations. Induced velocities from two different data banks were used to validate this method. ESA

A NOVEL CFD/STRUCTURAL ANALYSIS OF A CROSS PARACHUTE
R. A. LaFarge, J. M. Nelsen, and K. W. Gwinn 1993 11 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 11-14 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005271; SAND-93-3895C; CONF-940152-1) Avail: CASI HC A03/MF A01

A novel CFD/structural analysis was performed to predict functionality of a cross parachute under loadings near the structural limits of the parachute. The determination of parachute functionality was based on the computed structural integrity of the canopy and suspension lines. In addition to the standard aerodynamic pressure loading on the canopy, the structural analysis considered the reduction in fabric strength due to the computed aerodynamic heating. The intent was to illustrate the feasibility of such an analysis with the commercially available software PATRAN. DOE

HEAVE DYNAMICS OF AN AIR CUSHION VEHICLE BAG AND FINGER SKIRT M.S. Thesis
Joon Chung 1993 114 p
(ISBN-0-315-87053-2; CTN-94-61242) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A theoretical analysis of the heave dynamics of an air cushion vehicle bag and finger skirt is presented. The dynamic response of the skirt was predicted using a simplified model derived from Lagrange's equations. The skirt mass is lumped in the finger, and the fingers are modelled as rigid bodies having both mass and moment of inertia. The equations governing the dynamics of the bag and finger system and its interaction with cushion and craft systems are then derived. The theoretical model uses a simplified geometry and has two degrees of freedom. It is further developed to explore its ability to predict dynamic skirt responses. A system of nonlinear differential equations is solved by integration using Gear's method. The assumptions related to the fluid mechanics, skirt material properties, and skirt geometry used in the analysis are presented and the reasons for their choice are discussed. The theoretical results of the nonlinear heave response and the effect of both the skirt mass and changing skirt geometry on frequency response are detailed. Simulation results show that though air cushion dynamics are nonlinear as a whole, there are distinct segments which may be predicted by linear analysis. Author (CISTI)

NUMERICAL SIMULATION OF COMBINED EXTERNAL/INTERNAL TRANSONIC FLOW ON THE FOREBODY/INLET OF THE AV-8B HARRIER 2 Ph.D. Thesis
Stephen John Mysko, III 1993 117 p
Avail: Univ. Microfilms Order No. DA9320457

In this work, the computation of combined external/internal transonic flow on the complex forebody/inlet configuration of the AV-8B Harrier 2 is performed. The actual aircraft has been measured and its surface and surrounding domain have been defined using computational structured grids. The thin-layer Navier-Stokes equations were used to model the flow along with the Chimera overlaid multiblock technique. A fully conservative, alternating direction implicit (ADI), approximately-factored (two factors), partially flux-split algorithm was employed to perform the computation. Comparisons to some experimental data yielded good agreement for the simplifications incorporated into the analysis. The aim of the dissertation is to provide a methodology or computational tool for the numerical solution of complex flows, specifically combined external/internal flows. The use of embedded multiblocks enables easier definition of the geometry and also allows for single surfaces to be defined by more than one grid. The unique grid system must account for a geometry which has a fuselage and inlet which share a wall, and at the same time be able to model both external and internal flow. An existing code was altered to conform with the needs of the study, and a special boundary condition was developed and is presented. This boundary condition was used near the inlet engine face to improve the accuracy of the numerical model. The algorithm incorporates the Chimera technique and an algebraic turbulence model in order to deal with the overlaid multiblocks and viscous governing equations. The TFFS (two-factor, flux-split) scheme was applied to solve steady flows using the CRAY Y-MP supercomputer. The general flow quality was discussed and evaluated and any problem areas were expanded upon. The results for flow at zero incidence and angle of attack compared favorably with the experimental data both for local surface pressure data and globally over the entire engine face. In addition, the inlet back pressure boundary condition was employed to generate off-design flow characteristics. The results indicate the methodology used here is a viable tool for aircraft modeling. Dissert. Abstr.

ON AN ADAPTATION METHOD FOR 2-DIMENSIONAL C-TYPE GRIDS
P. W. J. vanHengel and M. A. Vis 1993 12 p Presented at ISNaS Symposium, Emmeloord, Netherlands, 19-20 Sep. 1991 Prepared in cooperation with National Aerospace Lab.
(W-9322; ETN-94-96183) Avail: CASI HC A03/MF A01

A practical application of an adaptive grid method for two dimensional C type grids around aerofoils is presented. The method was applied to adapt grids used for the simulation of inviscid flow (NACA 0012 aerofoil) and viscous flow (RAE 2822 aerofoil). It is concluded that the method is very well suited for grids with moderate aspect ratios as used for inviscid flow computations. High aspect ratio grids, as used for viscous flow computations, require more careful tuning of the parameters in the adaptation algorithm. ESA

N94-31828 Colorado Univ., Boulder.
A NEW INVERSE METHOD FOR GENERATING HIGH-SPEED AERODYNAMIC FLOWS WITH APPLICATION TO WAVERIDER DESIGN Ph.D. Thesis
Kevin Daniel Jones 1993 172 p
Avail: Univ. Microfilms Order No. DA9320435

The design of efficient high-speed aircraft is of considerable interest for use in a multitude of applications including civil transport, access to low earth orbit, and aeroassisted orbital transfer. The design of such vehicles is often accomplished with the aid of numerical methods. A new, numerical inverse-design method is developed for the principle lifting surface of such vehicles. Here the compressible three dimensional Euler equations are marched spatially away from a prescribed shock surface in a cross-stream direction to define the post-shock flowfield. The general three dimensional problem is mathematically ill-posed; however, by marching within the local osculating plane, accurate and stable solutions are obtained. The algorithm is applied to the design of a class of hypersonic vehicles called waveriders. The waverider's lower surface is defined as a stream surface carved from the post-shock flowfield computed by this marching procedure. The waverider's upper surface is a parametrically defined expansion surface, and the flowfield there is predicted by an approximation of the axisymmetric method of characteristics. Comparisons with exact theory and direct Euler simulations demonstrate the validity and accuracy of the method. The algorithm's application to waverider design affords much greater flexibility in the choice of shock shapes than any previous studies, including here the possibility of nonaxisymmetric shocks with nonconstant shock strengths. Dissert. Abstr.

N94-31879 Texas Univ., Arlington.
SHOCK IMPINGEMENT NEAR MILD HYPERSONIC EXPANSION CORNERS Ph.D. Thesis
Kung-Ming Chung 1992 151 p
Avail: Univ. Microfilms Order No. DA9315977

Experiments were performed in the UTA shock tunnel at Mach 8 and a Reynolds number of 10.2 million/m. A cold-wall, turbulent boundary layer developed along a long flat plate installed in the test section. An expansion corner of 2.5 deg or 4.25 deg was located at 0.77 meters (30.25 inches) from the leading edge of the flat plate. The test surface was instrumented for surface pressure measurement using flush-mounted, fast-response pressure transducers. Interactions were generated by full-span external shock generation in the form of a 2 deg or 4 deg sharp wedge. A hypersonic similarity parameter was identified which scaled the downstream influence of an expansion corner, indicating that the flow can be treated as primarily rotational and inviscid. The surface pressure fluctuations were severely damped by the expansion. The pressure distributions with shock impingement were strongly influenced by the presence of the expansion corners. The upstream influence scale decreased as the shock impinged further downstream of the corner. The unsteadiness of the shock wave/boundary layer interactions was characterized by an intermittent region together with a local rms pressure peak near the upstream influence line. Also, the peak rms pressure fluctuations increased with a larger overall inviscid pressure ratio. Dissert. Abstr.

N94-31880 Ohio State Univ., Columbus.
DESIGN AND INITIAL TESTING OF A FACILITY TO MEASURE UNSTEADY PRESSURES ON AN OSCILLATING CASCADE WITH SUPERSONIC LEADING EDGE LOCUS Ph.D. Thesis
Daniel Eugene Erwin 1993 156 p
Avail: Univ. Microfilms Order No. DA9316150

The development of analytical codes to predict the lift and moment coefficients on an airfoil in an oscillating cascade with a supersonic leading edge locus (SLEL) has generated a need to obtain unsteady experimental pressure data to validate the codes. A facility to gather such data was designed and constructed at the Ohio State University Aeronautical and Astronautical Research Laboratory, and unsteady pressure data was collected for a cascade oscillating at zero stagger angle. Unsteady pressures were measured for reduced frequencies ranging from .025 (26 Hz) to .159 (166 Hz), based on half chord. An experimental influence coefficient technique originally developed for subsonic and transonic cascades was extended to the case of a cascades with a SLEL. This technique was developed to obtain the unsteady pressure difference coefficient on an airfoil in a cascade of airfoils, all of which were executing constant amplitude oscillations at a constant interblade phase angle. This influence coefficient technique allowed the measurement of the pressures by oscillating one airfoil at a time. In order to extend the influence coefficient technique to the measurement of unsteady pressures on a cascades with a SLEL, it was first necessary to derive the equations applicable to a SLEL cascade. The unsteady pressure on a reference airfoil due to all of the airfoils oscillating was then the sum of the influence coefficients from each airfoil. Dissert. Abstr.

N94-31882 North Carolina State Univ., Raleigh.
BOUNDARY LAYER STUDY ON NOZZLE WALL AT HYPERSONIC VELOCITIES Ph.D. Thesis
Kenneth Morris Jones 1993 151 p
Avail: Univ. Microfilms Order No. DA9316605

The boundary layer on the wall of Naval Surface Warfare Center (NSWC) Hypervelocity Tunnel 9 has been investigated with pitot pressure and total temperature measurements. Experimental results are presented for standard Mach 14 runs and supercooled Mach 14 and Mach 18 runs. The experimental results are compared to numerical predictions made with

a modified Navier-Stokes algorithm including vibrational nonequilibrium and intermolecular force effects. The code uses the Cebeci-Smith turbulence model, which has real gas terms incorporated, to model the boundary layer. For standard Mach 14 conditions, the numerical solutions agree very well with experimental data. For the supercooled cases, the numerical code predicts the total temperature well; however, it over-predicts the pitot pressure. In all cases, the turbulence model significantly underestimated the boundary layer thickness and displacement thickness. A study of the method of characteristics/boundary layer technique to design hypersonic nozzles was also carried out. A Mach 18 nozzle was designed with this method and analyzed with the same Navier-Stokes code used to analyze the experimental data. The numerical analysis revealed that the nozzle generated a uniform, disturbance free core flow. Dissert. Abstr.

N94-31907 California Inst. of Tech., Pasadena.
TIP EFFECTS ON THE VORTEX WAKE OF AN AXISYMMETRIC BODY AT ANGLE OF ATTACK Ph.D. Thesis
David Henry Bridges 1993 186 p
Avail: Univ. Microfilms Order No. DA9316833

Experiments on the effects of conditions at the tip of an axisymmetric body on the vortex wake of the body at large angle of attack in incompressible flow have been performed. The separation patterns that occur at the nose of a cone with a hemispherical tip have been documented for ranges of Reynolds number based on tip radius and of relative angle of attack. Tips with cross sections that vary smoothly from elliptic to circular have been designed and tested on a cone. The effectiveness of the tips in varying the cone side force coefficient as the tip is rotated has been demonstrated. The relation between tip roll angle and side force coefficient has been shown to be essentially independent of Reynolds number, for the range of Reynolds number tested, as well as cone base conditions and roll direction. The relation between tip roll angle and side force coefficient has been shown to be a strong function of angle of attack. The reasons for nonsmooth variation of side force coefficient with tip roll angle at higher angles of attack have been determined by examinations of the vortex wake geometry. Peaks in the magnitude of the side force coefficient after zero crossings have been shown to be caused by a rapid shift in the wake vortices away from a symmetric configuration as the tip rotates away from a symmetry condition. Reductions in magnitude of the ride force coefficient between magnitude peaks have been demonstrated to be a result of the near vortex crossing over the cone centerline. This vortex crossover has been shown to occur near and after the breakaway from the cone of the far vortex. The ability of one of the elliptic cross section tips to produce smooth variations of side force coefficient with roll angle ahead of vortex breakaway has been demonstrated, suggesting that the tip might be an effective yaw control device for aircraft at high angle of attack. Dissert. Abstr.

N94-31958 Stanford Univ., CA.
VIBRATIONAL ENERGY TRANSFER OF DIATOMIC GASES IN HYPERSONIC EXPANDING FLOWS Ph.D. Thesis
Stephen Merrick Ruffin 1993 196 p
Avail: Univ. Microfilms Order No. DA9326551

In high temperature flows related to vehicles at hypersonic speeds significant excitation of the vibrational energy modes of the gas can occur. Accurate predictions of the vibrational state of the gas and the rates of vibrational energy transfer are essential to achieve optimum engine performance, for design of heat shields, and for studies of ground based hypersonic test facilities. The Landau-Teller relaxation model is widely used because it has been shown to give accurate predictions in vibrationally heating flows such as behind forebody shocks. However, a number of experiments in nozzles have indicated that it fails to accurately predict the rate of energy transfer in expanding, or cooling, flow regions and fails to predict the distribution of energy in the vibrational quantum levels. The present study examines the range of applicability of the Landau-Teller model in expanding flows and develops techniques which provide accurate predictions in expanding flows. In the present study, detailed calculations of the vibrational relaxation process of N2 and CO in cooling flows are conducted. A coupled set of vibrational transition rate equations and quasi one dimensional fluid dynamic equations is solved. Rapid anharmonic vibration translation transition rates and vibration-vibration exchange collisions are found to be responsible for vibrational relaxation acceleration in situations of high vibrational temperature and low translational temperature. The predictions of the detailed master equation solver are in excellent agreement with experimental results. The exact degree of acceleration is cataloged in this study for N2 and is found to be a function of both the translational temperature (T) and the ratio of vibrational to translational temperatures (T(sub vib)/T). Non-Boltzmann population distributions are observed for values of T(sub vib)/T as low as 2.0. The local energy transfer rate is shown to be an order of magnitude or more faster than the Landau-Teller model for more extreme cases of thermal nonequilibrium. However, these large degrees of local acceleration are difficult to observe in gas dynamic flows because the vibrational energy becomes frozen in rapid expansions. The Landau-Teller model fails to predict non-Boltzmann population distributions for even moderate degrees of thermal nonequilibrium but only fails to accurately predict the overall amount energy in vibration for flows which both have high values of T(sub vib)/T and are not vibrationally frozen. A simplified relaxation model is developed which allows both non-Boltzmann population distributions and includes anharmonic transition rates and energy transfer. Although the simplified anharmonic model requires significantly less computational time than the master equation solver it gives good agreement with the detailed solver and with experimental test results. Dissert. Abstr.

A STUDY OF THE DEVELOPMENT AND ATTENUATION OF WING-GENERATED, VORTICAL WAKES Ph.D. Thesis
Vojin Rade Nikolic 1993 255 p
Avail: Univ. Microfilms Order No. DA9319292

Lift-generated wake vortices trailing behind present-day heavy aircraft are of great concern to the aviation community, because they can pose a hazard to a following aircraft that inadvertently penetrates the wake. In order to address the problem of wake-vortex alleviation in a systematic way, an inviscid three dimensional model for calculation of the roll up of wing vortex wakes was developed. The code was extensively tested and validated using a large body of theoretical, computational, and experimental results. During the validation, it was shown that the second moment of vorticity, heretofore assumed to be constant, not only changes as the wake evolves, but must do so in order to conserve energy. Further, the second moment of vorticity has been shown to be a reliable measure of the completeness of the wake roll up process. Found efficient and reliable, the computer code has been applied to computationally investigate some alleviation schemes suggested in the literature as well as some original concepts. It was demonstrated that tailoring the wing spanwise load distribution by use of flaps modifies the resulting wake in terms of making it both more diffuse and, by mooring the primary vortices closer together, renders it more susceptible to the 'Crow' far field instability. Although injection of counter-rotating (with respect to the wing tip vortex) vortices showed little merit, injection of corotating discrete midspan vortices both changes the roll up pattern and hastens the far field instability (from a separation point of view), but causes induced drag penalties. As a completely new idea, excitation of the far field instability of the main wing-vortex pair by injecting relatively weak, intermediate-span, discrete vortices was investigated. During the course of this last investigation, a new method of determining the character of vortex entrainment was developed and shown to be viable. The result of this excitation investigation showed that injection of single, relatively weak, corotating discrete vortices near 0.5 semispans on the left and right side of the wing effectively excited the far field, most-unstable wavelength. The optimal wing location for vortex injection was shown to be only weakly dependent on vortex strength. These findings appear to be compatible with some experimental results from the literature, although the authors of the article containing these results offer an alternative explanation for the mechanism responsible for their results. In fact, the work of this dissertation shows that the alternative explanation appears to be incorrect. Additionally, in an unrelated investigation performed as part of this dissertation research, it was confirmed that the wake roll up can be disorganized by implementing positive bound-circulation gradients near wing tips; however, this benefit was offset by high drag and weight penalties.

SHOCK-DEPENDENT, OPTIMUM THRUST WINGS IN SUPERSONIC FLOW Ph.D. Thesis
James Lee Pittman 1993 141 p
Avail: Univ. Microfilms Order No. DA9318335

This study proposes a new wing concept that reduces the inviscid drag of a wing in supersonic flow. This wing concept contours the surface of each streamwise airfoil aft of the maximum thickness location to produce a significant thrust force thereby reducing the inviscid drag of the wing. The effectiveness of the thrust-wing concept is dependent upon the occurrence of a secondary shock on the wing surface. The secondary shock is clearly identified and exploited herein for the first time. The thrust-wing concept was evaluated on delta wing planforms and compared with delta wings using modified NACA 4-digit airfoils at M(sub infinity) = 1.60. The basic wing camber surface is a spanwise circular arc. The primary figure of merit for the evaluation was the inviscid drag coefficient as computed by a full-potential flow solver for supersonic flow, NCOREL. A design procedure was developed to calculate a feasible, optimum thrust wing at a specified Mach number and lift coefficient for a given planform. The optimization algorithm was the Method of Feasible Directions as found in the CONMIN program. The optimization for a 60 degree delta wing at M(sub infinity) = 1.60 yielded a thrust wing with 17 percent lower inviscid drag at CL = 0.1 compared to the corresponding wing that utilized a modified NACA 4-digit airfoil. At C(sub L) = 0.3, a 9 percent inviscid drag reduction was obtained. Dissert. Abstr.

A CRITICAL ASSESSMENT OF UH-60 MAIN ROTOR BLADE AIRFOIL DATA

Joseph Totah Sep. 1993 24 p Presented at the 11th Annual Applied Aerodynamics Meeting, Monterey, CA, 9-13 Aug. 1993 See also A93-47210

(RTOP 505-59-36)

(NASA-TM-103985; A-93004; NAS 1.15:103985) Avail: CASI HC A03/MF A01

Many current comprehensive rotorcraft analyses employ lifting-line methods that require main rotor blade airfoil data, typically obtained from wind tunnel tests. In order to effectively evaluate these lifting-line methods, it is of the utmost importance to ensure that the airfoil section data are free of inaccuracies. A critical assessment of the SC1095 and SC1094R8 airfoil data used on the UH-60 main rotor blade was performed for that reason. Nine sources of wind tunnel data were examined, all of which contain SC1095 data and four of which also contain SC1094R8 data. Findings indicate that the most accurate data were generated in 1982 at the 11-Foot Wind Tunnel Facility at NASA Ames Research Center and in 1985 at the 6-inch by 22-inch transonic wind tunnel facility at Ohio State University. It has not been determined if data from these two sources are sufficiently accurate for their use in comprehensive rotorcraft analytical models of the UH-60. It is recommended that new airfoil tables be created for both airfoils using the existing data. Additional wind tunnel experimentation is also recommended to provide high quality data for correlation with these new airfoil tables. Author (revised)

AN EXPERIMENTAL STUDY OF THE FLOWFIELD ON A SEMISPAN RECTANGULAR WING WITH A SIMULATED GLAZE ICE ACCRETION Ph.D. Thesis, 1993 Final Report

Abdollah Khodadoust Cleveland, OH NASA Apr. 1994 249 p Original contains color illustrations

(Grant NAG3-1134; RTOP 505-68-10)

(NASA-CR-195301; E-8693; NAS 1.26:195301) Avail: CASI HC A11/MF A03; 7 functional color pages

Wind tunnel experiments were conducted in order to study the effect of a simulated glaze ice accretion on the flowfield of a semispan, reflection-plane, rectangular wing at Re = 1.5 million and M = 0.12. A laser Doppler velocimeter was used to map the flowfield on the upper surface of the model in both the clean and iced configurations at alpha = 0, 4, and 8 degrees angle of attack. At low angles of attack, the massive separation bubble aft of the leading edge ice horn was found to behave in a manner similar to laminar separation bubbles. At alpha = 0 and 4 degrees, the locations of transition and reattachment, as deduced from momentum thickness distributions, were found to be in good agreement with transition and reattachment locations in laminar separation bubbles. These values at y/b = 0.470, the centerline measurement location, matched well with data obtained on a similar but two dimensional model. The measured velocity profiles on the iced wing compared reasonably with the predicted profiles from Navier-Stokes computations. The iced-induced separation bubble was also found to have features similar to the recirculating region aft of rearward-facing steps. At alpha = 0 degrees and 4 degrees, reverse flow magnitudes and turbulence intensity levels were typical of those found in the recirculating region aft of rearward-facing steps. The calculated separation streamline aft of the ice horn at alpha = 4 degrees, y/b = 0.470 coincided with the locus of the maximum Reynolds normal stress. The maximum Reynolds normal stress peaked at two locations along the separation streamline. The location of the first peak-value coincided with the transition location, as deduced from the momentum thickness distributions. The location of the second peak was just upstream of reattachment, in good agreement with measurements of flows over similar obstacles. The intermittency factor in the vicinity of reattachment at alpha = 4 degrees, y/b = 0.470, revealed the time-dependent nature of the reattachment process. The size and extent of the separation bubble were found to be a function of angle of attack and the spanwise location. Three dimensional effects were found to be strongest at alpha = 8 degrees. The calculated separation and stagnation streamlines were found to vary little with spanwise location at alpha = 0 degrees. The calculated separation streamlines at alpha = 4 degrees revealed that the bubble was largest near the centerline measurement plane, whereas the tip-induced vortex flow and the model root-tunnel wall boundary-layer interaction reduced the size of the bubble. These effects were found to be most dramatic at alpha = 8 degrees. Author (revised)

A NOVEL POTENTIAL/VISCOUS FLOW COUPLING TECHNIQUE FOR COMPUTING HELICOPTER FLOW FIELDS Final Report, 16 Mar. 1990 - 26 May 1993

J. Michael Summa, Daniel J. Strash, and Sungyul Yoo 21 Jun. 1993 89 p

(Contract NAS2-13194; SBIR-02.09-9090)

(NASA-CR-193272; NAS 1.26:193272; AMI-9304) Avail: CASI HC A05/MF A01

The primary objective of this work was to demonstrate the feasibility of a new potential/viscous flow coupling procedure for reducing computational effort while maintaining solution accuracy. This closed-loop, overlapped velocity-coupling concept has been developed in a new two-dimensional code, ZAP2D (Zonal Aerodynamics Program - 2D), a three-dimensional code for wing analysis, ZAP3D (Zonal Aerodynamics Program - 3D), and a three-dimensional code for isolated helicopter rotors in hover, ZAPR3D (Zonal Aerodynamics Program for Rotors - 3D). Comparisons with large domain ARC3D solutions and with experimental data for a NACA 0012 airfoil have shown that the required domain size can be reduced to a few tenths of a percent chord for the low Mach and low angle of attack cases and to less than 2-5 chords for the high Mach and high angle of attack cases while maintaining solution accuracies to within a few percent. This represents CPU time reductions by a factor of 2-4 compared with ARC2D. The current ZAP3D calculation for a rectangular plan-form wing of aspect ratio 5 with an outer domain radius of about 1.2 chords represents a speed-up in CPU time over the ARC3D large domain calculation by about a factor of 2.5 while maintaining solution accuracies to within a few percent. A ZAPR3D simulation for a two-bladed rotor in hover with a reduced grid domain of about two chord lengths was able to capture the wake effects and compared accurately with the experimental pressure data. Further development is required in order to substantiate the promise of computational improvements due to the ZAPR3D coupling concept. Author

AERODYNAMIC DRAG OF DROPLETS IN TURBULENT FLOW FIELDS Ph.D. Thesis

William David Warnica 1992 166 p

(ISBN-0-315-75827-9) Avail: Univ. Microfilms Order No. DANN75827

The primary objectives of this research were to design, construct, and test an experimental apparatus which introduces liquid droplets into co-flowing, turbulent, gaseous fields under controlled and measurable conditions and to measure the drag of nonevaporating droplets in turbulent flow fields and parametric ranges relevant to spray combustion, as characterized by the Reynolds number, and the intensity and spatial scales of turbulence. Measured drag coefficients are required for use in computational models of equipment such as gas-turbine combustion

chambers where flame characteristics and combustion performance are strongly dependent on the manner in which droplets are transported and evaporated. Current computational models use drag coefficients of solid spheres in a quiescent field because the effects of turbulence on drag are not well defined, especially at Reynolds numbers characteristic of spray combustion. The experimental apparatus comprised a wind tunnel and a unique piezoelectric droplet generator. The experimental procedure was to inject water droplets of uniform size co-currently and continuously with vertical turbulent air flows while droplet velocities were measured at different elevations using laser Doppler velocimetry. Turbulence was characterized using hot-wire anemometry prior to droplet injection. Drag coefficients were calculated using these main measurements and the law of conservation of mechanical energy. This experimental methodology provided an effective means of determining the drag of droplets. There was no experimental evidence that the drag of droplets in turbulent fields is significantly different than that of solid spheres in a quiescent field at the same Reynolds number. The total measurement uncertainty of this result was approximately 30 percent. Reynolds numbers were investigated in the range 10 to 100, in terms of the equivalent spherical diameter of a droplet, and the mean relative velocity between the ambient gaseous field and droplets. Weber numbers were much less than unity so that droplets were effectively spherical. Relative intensities of turbulence were investigated in the range 0 to 100 percent, in terms of the mean relative velocity. Spatial scales of turbulence were large in comparison to the droplets so that the ratio between the spatial integral scale and droplet diameter was in the range 4 to 20. Dissert. Abstr.

STUDY OF DYNAMIC STALL PHENOMENON AND ITS CONTROL USING VORTICITY, STREAM FUNCTION AND CIRCULATION FORM OF THE UNSTEADY NAVIER-STOKES EQUATIONS Ph.D. Thesis

Junho Yang 1993 156 p

Avail: Univ. Microfilms Order No. DA9319276

An unsteady Navier-Stokes (NS) analysis is developed for studying flow past a maneuvering body. The present inclusion of circulation in the vorticity-stream function formulation of the unsteady NS analysis makes it feasible, for the first time, to correctly simulate the asymptotic far-field boundary condition. In the overall analysis, a clustered conformal mesh with C-grid topology is used, with the governing differential equations being solved using the implicit ADI-BGE technique. The effects of grid size and clustering on the flow solution, and the effect of grid stretching on the far-field solution, are studied using the flow configuration with Re = 45,000 and constant-rate pitch-up motion, with dot-alpha(exp +) = 0.2. The influence of the various initial states considered on this flow field is also carefully examined. The results obtained for this case compare very satisfactorily with the available experimental data. Other numerical results are also used to carefully validate the analysis developed here. An active control strategy in terms of modulated suction/injection (MSI) applied at the airfoil surface and its effect on the aerodynamic forces are studied and extended to various dot-alpha(exp +) motions, and, to some extent, different Re flows. Finally, an MSI control law for a constant-rate pitch-up motion is developed. The results obtained using this control law provide very optimal control of the unsteady separation process and subsequent formation of the dynamic-stall vortex and leads to an increase in lift and reduction in drag. A FINITE-DIFFERENCE APPROXIMATE-FACTORIZATION ALGORITHM FOR SOLUTION OF THE UNSTEADY TRANSONIC SMALL-DISTURBANCE EQUATION

John T. Batina Jan. 1992 38 p

(RTOP 505-63-50-12)

(NASA-TP-3129; L-16781; NAS 1.60:3129) Avail: CASI HC A03/MF A01

A time-accurate approximate-factorization (AF) algorithm is described for solution of the three-dimensional unsteady transonic small-disturbance equation. The AF algorithm consists of a time-linearization procedure coupled with a subiteration technique. The algorithm is the basis for the Computational Aeroelasticity Program-Transonic Small Disturbance (CAP-TSD) computer code, which was developed for the analysis of unsteady aerodynamics and aeroelasticity of realistic aircraft configurations. The paper describes details on the governing flow equations and boundary conditions, with an emphasis on documenting the finite-difference formulas of the AF algorithm. Author

(RTOP 505-60-21)

(NASA-TM-4387; H-1774; NAS 1.15:4387) Avail: CASI HC A03/MF A01

A flight experiment to test and evaluate the skin friction drag characteristics of a riblet surface in turbulent flow at supersonic speeds was conducted at NASA Dryden. Riblets of groove sizes 0.0030 and 0.0013 in. were mounted on the F-104G flight test fixture. The test surfaces were surveyed with boundary layer rakes and pressure orifices to examine the boundary layer profiles and pressure distributions of the flow. Skin friction reductions caused by the riblet surface were reported based on measured differences of momentum thickness between the smooth and riblet surfaces obtained from the boundary layer data. Flight test results for the 0.0030 in. riblet show skin friction reductions of 4 to 8 % for Mach numbers ranging from 1.2 to 1.6 and Reynolds numbers ranging from 2 to 3.4 million per unit foot. The results from the 0.0013 in. riblets show skin friction reductions of 4 to 15 % for Mach 1.2 to 1.4 and Reynolds numbers ranging from 3.6 to 6 million per unit foot. Author

Avail: CASI HC A03/MF A01

A generalized flow solver using an implicit Lower-upper (LU) diagonal decomposition based numerical technique has been coupled with three low-Reynolds number kappa-epsilon models for analysis of problems with engineering applications. The feasibility of using the LU technique to obtain efficient solutions to supersonic problems using the kappa-epsilon model has been demonstrated. The flow solver is then used to explore limitations and convergence characteristics of several popular two equation turbulence models. Several changes to the LU solver have been made to improve the efficiency of turbulent flow predictions. In general, the low-Reynolds number kappa-epsilon models are easier to implement than the models with wall-functions, but require much finer near-wall grid to accurately resolve the physics. The three kappa-epsilon models use different approaches to characterize the near wall regions of the flow. Therefore, the limitations imposed by the near wall characteristics have been carefully resolved. The convergence characteristics of a particular model using a given numerical technique are also an important, but most often overlooked, aspect of turbulence model predictions. It is found that some convergence characteristics could be sacrificed for more accurate near-wall prediction. However, even this gain in accuracy is not sufficient to model the effects of an external pressure gradient imposed by a shock-wave/ boundary-layer interaction. Additional work on turbulence models, especially for

compressibility, is required since the solutions obtained with base line turbulence are in only reasonable agreement with the experimental data for the viscous interaction problems. Author

FOURTH-ORDER 2N-STORAGE RUNGE-KUTTA SCHEMES
Mark H. Carpenter and Christopher A. Kennedy Jun. 1994 26 p
(RTOP 505-70-62-13)
(NASA-TM-109112; NAS 1.15:109112) Avail: CASI HC A03/MF A01

A family of five-stage fourth-order Runge-Kutta schemes is derived; these schemes required only two storage locations. A particular scheme is identified that has desirable efficiency characteristics for hyperbolic and parabolic initial (boundary) value problems. This scheme is competitive with the classical fourth-order method (high-storage) and is considerably more efficient and accurate than existing third-order low-storage schemes. Author

An on-demand wing vortex control system includes a pair of retractable panels which extend forward through slots in the leading edges of the strake and main wing at their junction. When not in use, the device is retracted in a stowed position, thus having zero impact on the cruise efficiency and observability characteristics designed into the aircraft. The panels extend forward from the strake and wing, providing an added leading edge airfoil surface when in the deployed position. Both panels are slideably and rotatably affixed to the aircraft. A front panel is affixed to and supported within the strake, while a rear panel is affixed and supported within the main wing. The planform of each panel is symmetrically identical, and the movements of the panels are mechanically coordinated. DTIC

Avail: CASI HC A03/MF A01

Flows through three reference nozzles have been calculated to determine the capabilities and limitations of the widely used Navier-Stokes solver, PARC. The nozzles examined have similar dominant flow characteristics as those considered for supersonic transport programs. Flows from an inverted velocity profile (IVP) nozzle, an under expanded nozzle, and an ejector nozzle were examined. PARC calculations were obtained with its standard algebraic turbulence model, Thomas, and the two-equation turbulence model, Chien k-epsilon. The Thomas model was run with the default coefficient of mixing set at both 0.09 and a larger value of 0.13 to improve the mixing prediction. Calculations using the default value substantially underpredicted the mixing for all three flows. The calculations obtained with the higher mixing coefficient better predicted mixing in the IVP and underexpanded nozzle flows but adversely affected PARC's convergence characteristics for the IVP nozzle case. The ejector nozzle case did not converge with the Thomas model and the higher mixing coefficient. The Chien k-epsilon results were in better agreement with the experimental data overall than were those of the Thomas run with the default mixing coefficient, but the default boundary conditions for k and epsilon underestimated the levels of mixing near the nozzle exits. CONTROL OF LOW-SPEED TURBULENT SEPARATED FLOW OVER A BACKWARD-FACING RAMP Ph.D. Thesis - Old Dominion Univ.
John C. Lin May 1992 204 p
(NASA-TM-109740; NAS 1.15:109740) Avail: CASI HC A10/MF A03

The relative performance and flow phenomena associated with several devices for controlling turbulent separated flow were investigated at low speeds. Relative performance of the devices was examined for flow over a curved, backward-facing ramp in a wind tunnel, and the flow phenomena were examined in a water tunnel using dye-flow visualization. Surface static pressure measurements and oil-flow visualization results from the wind tunnel tests indicated that transverse grooves, longitudinal grooves, submerged vortex generators, vortex generator jets (VGJ's), Viets' fluidic flappers, elongated arches at positive angle of attack, and large-eddy breakup devices (LEBU's) at positive angle of attack placed near the baseline separation location reduce flow separation and increase pressure recovery. Spanwise cylinders reduce flow separation but decrease pressure recovery downstream. Riblets, passive porous surfaces, swept grooves, Helmholtz resonators, and arches and LEBU's with angle of attack less than or = 0 degrees had no significant effect in reducing the extent of the separation region. Wall-cooling computations indicated that separation delay on a partially-cooled ramp is nearly the same as on a fully-cooled ramp, while minimizing the frictional drag increase associated with the wall cooling process. Dry-flow visualization tests in the water tunnel indicated that wishbone vortex generators in the forward orientation shed horseshoe vortices; wishbone vortex generators oriented in the reverse direction and doublet vortex generators shed streamwise counterrotating vortices; a spanewise cylinder located near the wall and LEBU's at angle of attack = -10 degrees produced eddies or transverse vortices which rotated with the same sign as the mean vorticity in a turbulent boundary layer; and the most effective VGJ's produced streamwise co-rotating vortices. Comparative wind-tunnel test results indicated that transferring momentum from the outer region of a turbulent boundary layer through the action of embedded streamwise vortices is more effective than by transverse vortices for the separation control application studied herein. THE ANALYSIS OF WAKE-INDUCED UNSTEADY AERODYNAMICS RELATED TO HIGHER HARMONIC CONTROL Ph.D. Thesis
Ahmed A. Abourahma Dec. 1993 165 p
(AD-A277914) Avail: CASI HC A08/MF A02

Performance data from the NASA-Army OH-6A higher harmonic control (HHC) flight test program showed significant reductions in main rotor shaft torque and engine power in hover and forward flight 1. The unsteady aerodynamics with the higher harmonic control system application, including wake effects. were considered to study whether such power reductions are feasible. An airfoil oscillating in pure plunge can achieve propulsive force (Katzmayr effect), as in the case of birds' wings flapping in flight. Here it will be shown that this effect can be enhanced in the presence of layers of shed vorticity with the proper phasing. In addition, while it is known that an airfoil oscillating in pitch, will typically produce drag at most values of reduced frequency, it is found that the presence of another layer of shed vorticity of the proper phase, can reduce the drag on the pitching airfoil depending upon wake spacing reduced frequency, and phase. Under some conditions the added layer or layers of shed vorticity will even result in propulsive force acting on the pitching airfoil similar to the Katzmayr effect for the plunging case. It was found, for the OH-6A helicopter, that the measured reductions in main rotor shaft torque and engine power are feasible when evaluated with respect to the Katzmayr effect and the additional drag reduction or propulsive force obtained due to pitch and plunge oscillations with the effect of adjacent wake layers of shed vorticity. INSTALLED F/A-18 INLET FLOW CALCULATIONS AT 30 DEGREES ANGLE-OF-ATTACK: A COMPARATIVE STUDY Final Report
C. Frederic Smith and Steve D. Podleski Cleveland, OH NASA Apr. 1994 51 p
(Contract NAS3-25266; RTOP 505-68-30)
(NASA-CR-195297; E-8678; NAS 1.26:195297) Avail: CASI HC A04/MF A01

NASA Lewis is currently engaged in a research effort as a team member of the High Alpha Technology Program (HATP) within NASA. This program utilizes a specially equipped F/A-18, the High Alpha Research Vehicle (HARV), in an ambitious effort to improve the maneuverability of high-performance military aircraft at low subsonic speed, high angle of attack conditions. The overall objective of the Lewis effort is to develop

inlet technology that will ensure efficient airflow delivery to the engine during these maneuvers. One part of the Lewis approach utilizes computational fluid dynamics codes to predict the installed performance of inlets for these highly maneuverable aircraft. Full Navier-Stokes (FNS) calculations on the installed F/A-18 inlet at 30 degrees angle of attack, 0 degrees yaw, and a freestream Mach number of 0.2 have been obtained in this study using an algebraic turbulence model with two grids (original and revised). Results obtained with the original grid were used to determine where further grid refinements and additional geometry were needed. In order to account properly for the external effects, the forebody, leading edge extension (LEX), ramp, and wing were included with inlet geometry. In the original grid, the diverter, LEX slot, and leading edge flap were not included due to insufficient geometry definition, but were included in a revised grid. In addition, a thin-layer Navier-Stokes (TLNS) code is used with the revised grid and the numerical results are compared to those obtained with the FNS code. The TLNS code was used to evaluate the effects on the solution using a code with more recent CFD developments such as upwinding with TVD schemes versus central differencing with artificial dissipation. The calculations are compared to a limited amount of available experimental data. The predicted forebody/fuselage surface static pressures compared well with data of all solutions. The predicted trajectory of the vortex generated under the LEX was different for each solution. These discrepancies are attributed to differences in the grid resolution and turbulence modeling. All solutions predict that this vortex is ingested by the inlet. The predicted inlet total pressure recoveries are lower than data and the distortions are higher than data. The results obtained with the revised grid were significantly improved from the original grid results. The original grid results indicated the ingested vortex migrated to the engine face and caused additional distortions to those already present due to secondary flow development. The revised grid results indicate that the ingested vortex is dissipated along the inlet duct inboard wall. The TLNS results indicate the flow at the engine face was much more distorted than the FNS results and is attributed to the pole boundary condition introducing numerical distortions into the flow field. A NEW METHOD FOR CALCULATING WING ALONG AERODYNAMICS TO ANGLE OF ATTACK 180 DEG
Roy M. McInville and Frank G. Moore Mar. 1994 65 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277965; NSWCDD/TR-94/3) Avail: CASI HC A04

A new semiempirical method has been developed to estimate wing alone aerodynamics at all Mach numbers and angles of attack (AOA) encountered in flight. The method utilizes the slender body or linearized theories at low AOA and several wing alone data bases at higher AOA. In areas where data is not available, extrapolations and interpolations are used with existing data. The new method is shown to be more accurate than the second-order technique developed for the 1993 version of the NSWCDD Aeroprediction Code (AP93) over the AOA range of 0 to 30 degrees where that technique is applicable. More importantly, however, is the fact that the new method allows AOA to 180 deg. As a result, this new wing alone method forms the first step in expanding the AP93 to higher AOA than 30 degrees. DEVELOPMENT OF A THREE-DIMENSIONAL ICING MODEL FOR PREDICTING ICE ACCRETION ON AIRCRAFT Ph.D. Thesis - Clermont-Ferrand II Univ. [MODELISATION TRIDIMENSIONNELLE DES DEPOTS DE GIVRE SUR LES VOILURES D'AERONEFS]
Thierry Hedde 1993 148 p In FRENCH
(ISSN 0078-3781)
(ONERA-NT-1993-5; ETN-94-95874) Avail: CASI HC A07/MF A02

The development of a three dimensional icing code is described. Nonviscous flows may be calculated using either the Euler method, especially in the transonic domain, or the panel method, mainly for multistep ice accretion calculations. A Van Driest roughness model was implemented in the turbulent boundary layer calculation, and yields realistic values of the heat transfer coefficient. The estimation of the runback equation terms shows that the air/water interface shear stress is the leading one. A new grid built up along the runback paths can be used to establish the thermodynamic balance and calculate the ice thickness. The qualities of the model at high velocities (150 to 300 m/s) can be seen by comparison of the simulated ice shapes with the experimental shapes obtained on a parabolic rotor blade tip. Comparison with 'lobster tails' ice shapes grown on a swept NACA 0012 airfoil at low speed (70 m/s) shows the model's limits. The 'lobster tails' accretion is explained by way of droplet scale shadowing phenomena, and by local variation of the heat transfer coefficient. A ballistic model simulates the lobster tail accretion well, although only qualitatively, due to lack of experimental data. ESA

This report documents Phase II of a two-phase effort to examine rotorcraft ditchings and water-related impacts for rotorcraft, that occurred between the years 1982 through 1989. The main tasks performed for this phase of the investigation were assessment of the effects of structure on occupant injury, determination of the specific modes of structural failure, identification of the potential means to alleviate injury, and evaluation of available analytical methods for modeling rotorcraft water impacts. The Phase II analysis examined specific aspects of the Phase I data for accidents that fulfilled the criteria for the three impact scenarios. The main impact injuries were from flailing and excessive acceleration and resulted from occupant interaction with the rotorcraft interior and insufficient energy absorption. Drowning and exposure were found to be the main post-impact hazards and other post-impact injuries were minor in severity. Structural failures of the rotorcraft are identified and discussed as they affected occupant injury. The performance and adequacy of rotorcraft flotation equipment is discussed. Means of alleviating occupant injury in rotorcraft water impacts are identified and discussed. An analytical method for modeling the water impact of a rotorcraft is evaluated. DTIC

AIRCRAFT ICING HANDBOOK (UPDATE) Final Report
1993 436 p Revised Sponsored by FAA
(AD-A276499) Avail: CASI HC A19/MF A04

The first update of the Aircraft Icing Handbook does not change the organization of the handbook into volumes and chapters as delineated on page 7. However, new sections have been added to Chapter 3: ice protection methods. Section 1.0 no longer contains information on pneumatic impulse deicing and has therefore been retitled: Section 1.0 - Conventional pneumatic boot deicing systems. Three new sections have been added: Section 1A.0 - pneumatic impulse deicing systems; Section 4A.0 - electro-explusive deicing systems; and Section 4B.0 - eddy current deicing systems. DTIC

WHIPICE (Videotape)
1992 Videotape: 8 min. 30 sec. playing time, in color, with sound
(NASA-TM-109749; NONP-VT-94-9949) Avail: CASI VHS A01/BETA A22

This video documents efforts by NASA Lewis Research Center researchers to improve ice protection for aircraft. A new system of deicing aircraft by allowing a thin sheet of ice to develop, then breaking it into particles, is being examined, particularly to determine the extent of shed ice ingestion by jet engines that results. The process is documented by a high speed imaging system that scans the breakup and flow of the ice particles at 1000 frames per second. This data is then digitized and analyzed using a computer program called WHIPICE, which analyzes grey scale images of the ice particles. Detailed description of the operation of this computer program is provided. CASI

SATCOM FEASIBILITY STUDY FOR SEARCH AND RESCUE AIRCRAFT Final Report
John Sydor and Jack Rigley Jan. 1993 131 p
(DSIS-94-01083; CTN-94-61214) Avail: CASI HC A07/MF A02

The feasibility of using satellite communications to improve the reliability of communications to search and rescue (SAR) aircraft throughout the Canadian SAR regions is examined. The primary satellite communications media considered are MSAT and Inmarsat. The main communications requirement for SAR aircraft operations is reliable voice communications throughout the SAR regions. Secondary or desirable requirements include global operations and security of voice and data communication. Both Inmarsat and MSAT systems were found capable of meeting the prime requirement. The differences between those two systems is most evident in the avionics and antennas required to access them. Inmarsat equipment is much larger and more expensive than the equivalent MSAT equipment, since the MSAT system (to become operational by 1995) will be more powerful and sensitive. However, MSAT aeronautical satcom terminals are not yet available and would have to be developed, most likely as a derivative of MSAT land mobile terminals. Analysis of Satcom installations for CC-130 and CH-113 SAR aircraft was completed for both Inmarsat and MSAT compatible avionics and antennas. Most currently available Inmarsat compatible equipment is feasible for the CC-130, while only the smaller sized MSAT antenna is feasible for the CH-113. Author (CISTI)

A COMPARISON OF MILITARY AND COMMERCIAL AIRCRAFT DEVELOPMENT Report, Aug. 1992 - Apr. 1993
Michael S. Mutty Apr. 1993 37 p
(AD-A276830; NDU/ICAF-93-F3) Avail: CASI HC A03/MF A01

When compared to the commercial sector, it takes the military almost four times longer to develop an aircraft. For example, Boeing Company developed the 767 jetliner in about four years whereas the Navy's next generation tactical aircraft, the AX, is expected to take 15 years to develop. This research paper examines both commercial and military approaches to aircraft development. The paper focuses on establishing whether or not commercial practices, where more cost effective, can be incorporated into the military acquisition system. The paper illustrates that aircraft development in the commercial and military are different for two fundamental reasons. First, military aircraft development exploits the latest untested developments in technology where the commercial sector relies only on existing technologies. Second, a commercial aircraft is developed for the single mission of ferrying passengers and cargo. Military aircraft are required to perform far more varied and different missions with each parameter driving its own unique challenge for design and testing. This research paper concludes that without similar mission requirements, there are few commercial applications that can be applied to military aircraft development. DTIC

ESTIMATING THE IMPACT OF CRASHWORTHINESS STANDARDS ON MORTALITY AND MORBIDITY EVENTS IN THE US ARMY ROTARY-WING AIRCRAFT MISHAPS Final Report
Samuel G. Shannon and Dennis F. Shanahan Sep. 1993 49 p
(DA Proj. 3M1-62787-A-878)
(AD-A277121; USAARL-93-37) Avail: CASI HC A03/MF A01

It is desirable to provide modern military helicopters with the maximum crashworthiness that is practical in order to reduce injury in helicopter crashes. Although crashworthy design features have been proven to be extremely effective in reducing morbidity and mortality, a penalty of increased weight and added procurement cost must be paid. Consequently, the degree of crashworthiness designed into an aircraft must be a tradeoff between economics, aircraft performance, and the perceived risk of injury. To help these judgments, it would be useful to develop a mathematical model capable of predicting morbidity outcomes for a given aircraft design. All crashes of five types of U.S. Army helicopters occurring between 1 Oct. 1979 and 30 Sep. 1991 were examined to determine crash conditions and morbidity and mortality outcomes. Analyses were conducted with logistic regression (LOGISTIC) for mortality, and the fit of the model was considered. DTIC

GLUTINOUS WATER: PROTECTING VERTICAL AND OVERHEAD SURFACES FROM FIRE SPREAD
Homer W. Carhart 28 Feb. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277280; NRL/MR/6180-94-7431) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Most of the water used in firefighting is not only wasted, it also contributes extensively to total damage. Water is an unusual chemical in that, due to hydrogen bonding, it is a liquid at room temperature and it also has a very high heat of evaporation. So, if one could make water adhere significantly to vertical and overhead surfaces, a great deal of fire protection could be bought because such surfaces could not get hotter than the boiling point of water (100 C) and a great deal of heat energy would be required to evaporate it. This can be accomplished by making water glutinous, either by making a foam (e.g. shaving cream) or by thickening it (e.g. gravy), or both. Calculations and experiment show that up to at least ten times greater fire protection could be achieved with only about 1/20 to 1/50 the amount of water. DTIC

ANNUAL REVIEW OF AIRCRAFT ACCIDENT DATA: US AIR CARRIER OPERATIONS, CALENDAR YEAR 1991
15 Apr. 1994 74 p
(PB94-158847; NTSB/ARC-94/01) Avail: CASI HC A04/MF A01

This publication presents the record of aviation accidents involving revenue operations of U.S. Air Carriers including Commuter Air Carriers and On Demand Air Taxis for calendar year 1991. The report is divided into three major sections according to the federal regulations under which the flight was conducted - 14 CFR 121, 125, 127, Scheduled 14 CFR 135, or Nonscheduled 14 CFR 135. In each section of the report tables are presented to describe the losses and characteristics of 1991 accidents to enable comparison with prior years. Author

AVIATION HUMAN FACTORS RESEARCH IN US UNIVERSITIES: POTENTIAL CONTRIBUTIONS TO NATIONAL NEEDS
R. Key Dismukes Mar. 1994 21 p
(RTOP 505-64-13)
(NASA-TM-108814; A-94060; NAS 1.15:108814) Avail: CASI HC A03/MF A01

Universities can and should make vital contributions to national needs in aviation human factors. However, to guide and utilize university research effectively we must understand what types of expertise and facilities universities can bring to bear on aviation problems. We should be aware of where relevant research is already underway and where untapped potential exists. How does the character of research in universities differ from and complement research in government and industry laboratories? What conditions would encourage universities to focus on national priorities and would promote high quality, relevant research? This paper attempts to address these issues. It is based on a survey conducted by the author, which included site visits to several universities, telephone interviews with faculty members at other universities, and a search of the aviation human factors research literature. CIVIL TILTROTOR MARKET PENETRATION: EFFECTS ON NORTHEAST CORRIDOR AIRPORT DELAY
Anny S. Cheung and Douglas Baart Feb. 1994 38 p
(AD-A277534; DOT/FAA/CT-TN94/1; FAA-AOR-100-94-001) Avail: CASI HC A03/MF A01

This report addresses the delay impacts resulting from replacing conventional aircraft services with civil tiltrotor (CTR) operations in the Northeast corridor at four CTR service levels. This analysis was conducted by using the National Airspace System performance analysis capability (NASPAC) simulation modeling system (SMS). Cost of delay savings were derived by using the cost of delay module. The result of this study will be used by the Vertical Flight Program Office (ARD-30) in assessing the benefits of the CTR operations in the Northeast corridor. DTIC

THREE DIMENSIONAL AUDIO VERSUS HEAD DOWN TCAS DISPLAYS
Durand R. Begault and Marc T. Pittman Mar. 1994 14 p
(Contract NCC2-327)
(NASA-CR-177636; A-94066; NAS 1.26:177636) Avail: CASI HC A03/MF A01

The advantage of a head up auditory display was evaluated in an experiment designed to measure and compare the acquisition time for capturing visual targets under two conditions: Standard head down traffic collision avoidance system (TCAS) display, and three-dimensional (3-D) audio TCAS presentation. Ten commercial airline crews were tested under full mission simulation conditions at the NASA Ames Crew-Vehicle Systems Research Facility Advanced Concepts Flight Simulator. Scenario software generated targets corresponding to aircraft which activated a 3-D aural advisory or a TCAS advisory. Results showed a significant difference in target acquisition time between the two conditions, favoring the 3-D audio TCAS condition by 500 ms. Author

RESULTS OF REAL-TIME TESTING AND DEMONSTRATION OF THE US ARMY CORPS OF ENGINEERS REAL-TIME ON-THE-FLY POSITIONING SYSTEM
Sally L. Frodge, Benjamin W. Remondi, and Dariusz Lapucha Feb. 1994 12 p
(AD-A276160; TEC-R-215) Avail: CASI HC A03/MF A01

The U.S. Army Corps of Engineers has been developing a GPS carrier phase based positioning system for hydrographic surveying and dredging since 1988. This system provides real-time three dimensional positions with horizontal and vertical accuracies better than one decimeter over ranges up to 20 kilometers from a single reference station without static initialization. The project has passed from concept development through feasibility studies, system analysis, resolution of carrier ambiguities on-the-fly (OTF), and on to final system integration. The real-time testing of the system began in Mar. of 1993 and public demonstrations of the system began in Oct. 1993. Testing of the system has been performed under varying operating conditions to evaluate the limits of OTF ambiguity resolution for precisely positioning moving platforms. Tests have shown that this system is capable of 1-3 centimeters in all three dimensions. This paper will discuss the results of the testing to date and briefly describe the OTF system. DTIC

AN INVESTIGATION OF AIRBORNE GPS/INS FOR HIGH ACCURACY POSITION AND VELOCITY DETERMINATION
H. Sun (Calgary Univ., Alberta.), M. E. Cannon (Calgary Univ., Alberta.), T. E. Owen, and M. A. Meindl 1993 9 p Presented at the Institute of Navigation National Technical Meeting, San Diego, CA, 24-26 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006139; SAND-93-2413C; CONF-940158-1) Avail: CASI HC A02/MF A01

An airborne test using a differential GPS-INS system in a Twin Otter was conducted by Sandia National Laboratories to assess the feasibility of using the integrated system for cm-level position and cm/s velocity. The INS is a miniaturized ring-laser gyro IMU jointly developed by Sandia and Honeywell while the GPS system consists of the NovAtel GPSCard(trademark). INS position, velocity and attitude data were computed using Sandia's SANDAC flight computer system and logged at 4 Hz and GPS data was acquired at a 1 Hz rate. The mission was approximately 2.5 hours in duration and the aircraft reached separations of up to 19 km from the base station. The data was post-processed using a centralized Kalman filter approach in which the double differenced carrier phase measurements are used to update the INS data. The INS position is in turn used to detect and correct GPS carrier phase cycle slips and also to bridge GPS outages. Results are presented for the GPS-only case and also for integrated GPS/INS. DOE

FLIGHT TECHNICAL ERROR FOR CATEGORY B NON-PRECISION APPROACHES AND MISSED APPROACHES USING NON-DIFFERENTIAL GPS FOR COURSE GUIDANCE Final Report, Apr. 1992 - Mar. 1993
M. S. Huntley, J. W. Turner, and R. Palmer Nov. 1993 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-142734; DOT-VNTSC-FAA-93-17; DOT/FAA/RD-93/17) Avail: CASI HC A04

The report documents and discusses the performance of twelve general aviation pilots who used nondifferential global positioning system (GPS) in a Beechcraft Baron to fly 93 category B approaches defined by GPS waypoints. The research reported here was part of the U.S. Federal Aviation Administration (FAA) GPS Overlay Project and provided the data required by the agency to implement phase 1 of the GPS satellite operational plan for category B nonprecision approaches. The data collection and analysis procedures described herein were developed with and approved by the FAA's Satellite Operations Implementation Team. It should be noted, however, that additional work would be required to prepare the data for use in the development of GPS TERPS. NTIS

ERROR ANALYSIS OF REAL-TIME AND POST-PROCESSED ORBIT DETERMINATION FOR THE GEOSAT FOLLOW-ON ALTIMETRIC SATELLITE USING GPS TRACKING Ph.D. Thesis
William Steven Schreiner 1993 145 p
Avail: Univ. Microfilms Order No. DA9320477

The global positioning system (GPS) has the capability to supply real-time and post-processed positioning of unprecedented accuracy for low earth orbiting (LEO) satellites. This thesis has evaluated the expected orbit accuracy of the U.S. Navy's Geosat Follow-On (GFO) altimetric satellite for real-time and post-processed modes of operation when using GPS tracking. There is an interest in using orbit solutions that are generated by an onboard GPS navigation processor to compute altimetric ocean surface heights for near real-time mesoscale studies. Numerical simulations were performed to evaluate the on-board GFO radial orbit error and demonstrated that the spectral content of the orbit error contained significant power at mesoscale frequencies. However, it was demonstrated that a fitting process utilizing analytical J2 orbit theory can remove this mesoscale frequency content and provide an ephemeris adequate for real-time mesoscale oceanographic studies. This fitting procedure was verified by processing on-board GPS orbit and altimeter data from the TOPEX/POSEIDON mission. Processing GPS pseudorange and carrier phase measurements in a post-processed mode will allow precise orbit determination based on dynamics, kinematics, and a combination of the two. However, when the Department of Defense (DoD) enables their policy of selective availability/anti-spoof (SA/A-S), this positioning precision will be degraded for non SA/A-S capable receivers because they will no longer be able to use a dual frequency mode of ionospheric calibration. There does exist a less precise single frequency mode of ionospheric calibration called differenced range versus integrated Doppler (DRVID). The DRVID technique has been studied through equation development and data analysis. The method of covariance analysis was used to determine the expected radial orbit accuracy of GFO for both dual and single frequency (DRVID) GPS receiver configurations when using dynamic, kinematic, and reduced dynamic tracking. These analyses showed that the GFO orbit can be determined to an accuracy below the decimeter level in the radial direction if a dual frequency GPS receiver is used with reduced dynamic tracking. A single frequency (DRVID) low data noise receiver configuration also showed the potential to reach decimeter level tracking of the radial height of GFO when reduced dynamic tracking is employed. Dissert. Abstr.

PLAN RECOGNITION FOR AN AIR TRAFFIC CONTROL SIMULATION Interim Report

Sep. 1993 102 p

(DSIS-94-01221; CTN-94-61217) Copyright Avail: CASI HC A06/MF A02

Experiments were conducted in which human subjects performed an air traffic control simulation. Based on the results of that experimental study, work was then started on designing and developing a system for recognizing and predicting the subjects' plans for the aircraft as they fly through the simulation airspace. In designing the experimental study, results were used from pilot research which suggested that it would be possible to bring naive subjects to a level of play so that their results could be used in the development of a system to predict reliably the plans of other future subjects in the simulation. The pilot research results were used to design an experiment to collect data for use in developing the plan recognizer. The experimental design and procedure used are described, as well as the simulation airspace and its properties. The highest level of decomposition of the plan recognizer is reviewed with respect to four elements of the system's architecture: an air traffic control simulation; a database of session statistics, initial information about aircraft and airports, interface action information, and abstract plans for aircraft; a Nexpert Object expert system, which operates in the background to access database information and infer plans; and a Hypercard display component.

PERFORMANCE ANALYSIS OF AN INTEGRATED GPS/INERTIAL ATTITUDE DETERMINATION SYSTEM M.S. Thesis - MIT

Wendy I. Sullivan May 1994 91 p

(Contract NAS9-18426)

(NASA-CR-188289; NAS 1.26:188289; CSDL-T-1227) Avail: CASI HC A05/MF A01

The performance of an integrated GPS/inertial attitude determination system is investigated using a linear covariance analysis. The principles of GPS interferometry are reviewed, and the major error sources of both interferometers and gyroscopes are discussed and modeled. A new figure of merit, attitude dilution of precision (ADOP), is defined for two possible GPS attitude determination methods, namely single difference and double difference interferometry. Based on this figure of merit, a satellite selection scheme is proposed. The performance of the integrated GPS/inertial attitude determination system is determined using a linear covariance analysis. Based on this analysis, it is concluded that the baseline errors (i.e., knowledge of the GPS interferometer baseline relative to the vehicle coordinate system) are the limiting factor in system performance. By reducing baseline errors, it should be possible to use lower quality gyroscopes without significantly reducing performance. For the cases considered, single difference interferometry is only marginally better than double difference interferometry. Finally, the performance of the system is found to be relatively insensitive to the satellite selection technique. Author (revised)

RELATIVE MOTION PINWHEEL Patent

Gary E. Streimer, inventor (to Navy) and Leslie P. Benda, inventor (to Navy) 30 Nov. 1993 6 p Filed 5 Oct. 1991

(AD-D016107; US-Patent-Appl-SN-956327; US-Patent-Class-33-1-SB)

Avail: US Patent and Trademark Office

An apparatus for visualizing relative motion between two moving objects in a two-dimensional plane is provided. A planar base has a first compass rose printed thereon. Rotatably attached to the center of the first compass rose is a means for indicating a present course of a first moving object relative to a true bearing indication on the first compass rose. A second moving object assembly consists of a second compass rose rotatably attached to a means for indicating a present course of the second moving object relative to a true bearing indication on the second compass rose. The true bearing indication on the second compass rose is aligned to be equivalent to the true bearing indication on the first compass rose. Attached at the centers of the first and second compass roses is a means for tethering the second moving object assembly to the first compass rose. The second compass rose is free to rotate about its center, and the second moving object assembly is free to revolve in a single plane around the center of the first compass rose. The tethering means indicates a lint of relative bearing from the first moving object to the second moving object. DTIC

REAL-TIME CENTIMETER POSITIONING WITH GPS: A SYSTEM DEVELOPED BY THE US ARMY CORPS OF ENGINEERS

Sally L. Frodge, Benjamin Remondi, and Dariusz Lapucha 11 Apr. 1994 11 p

(AD-A278152; R-223) Avail: CASI HC A03/MF A01

The United States Army Corps of Engineers has been developing a Global Positioning System (GPS) carrier phase based positioning system for hydrographic surveying and dredging since 1988. This system provides real-time three-dimensional positions with horizontal and vertical accuracies better than 1 decimeter over ranges up to 20 kilometers from a single reference station without static initialization. The project has passed from concept development through feasibility studies, system analysis, resolution of carrier ambiguities on-the-fly (OTF), to final system integration which is nearing completion. The real-time testing of the system began in March of 1993. This testing was performed under varying operating conditions to evaluate the limits of OTF ambiguity resolution for precisely positioning moving platforms. This paper summarizes the results of those tests. Early real-time tests performed have shown 1-3 centimeters in all three dimensions. The final design of the real-time system and its integration to hydrographic survey platforms are also discussed. DTIC

AN EVALUATION OF THREE GPS RECEIVERS FOR USE IN THE GPS SOUNDER Final Report, period ending Oct. 1993

K. D. Anderson Apr. 1994 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ONR Proj. R035S83)

(AD-A278157; NCCOSC/RDT/E-TR-1637) Avail: CASI HC A04

Three high performance, geodetic quality, Global Positioning System (GPS) receivers were tested at the Naval Command, Control and Ocean Surveillance Center RDT and E Division to evaluate their use in supporting

the GPS Sounder. These tests are focused on comparisons of the signal-to-noise ratio (SNR) of the GPS satellite is either rising or setting on the ocean horizon. Of primary interest is the ability of the receiver to lock onto and track the GPS signals when the satellite is at elevation angles of less than 1 degree. This requirement is unique to the GPS Sounder and is one of the most stressful conditions for receiving processing. In most applications, GPS signals never examined at ground-to-satellite elevation angles of less than about 15 degrees because of multipath effects on signal reception. However, the ability to lock onto and track the GPS signals in the presence of severe multipath conditions is crucial to the success of the GPS Sounder. DTIC

A LABORATORY STUDY OF MULTIPLE SITE DAMAGE IN FUSELAGE LAP SPLICES Final Report, Nov. 1989 - Feb. 1992
R. Mayville and M. Sigelmann Dec. 1993 107 p Sponsored by FAA
(AD-A276151; DOT-VNTSC-FAA-93-12; DOT/FAA/CT-93/74) Avail: CASI HC A06/MF A02

This report details an experimental study that was conducted to explore the causes of fuselage lap splice multiple site damage (MSD), which has been observed in several aging aircraft. MSD was partially responsible for the 1988 Aloha Airlines accident. A specimen was designed and tests were conducted to investigate the effects on MSD and fatigue of: (1) a terminating action repair; (2) simultaneous tension and shear; and (3) stress and several lap splice configurations. The results of over 120 tests were supported by finite element analysis, strain gage studies and statistics. DTIC

TESTING OPERATIONAL FLIGHT PROGRAMS (OFP'S) Final Report, 10 - 13 May 1993
Charles P. Satterthwaite Feb. 1994 13 p
(AF Proj. 9994)
(AD-A276361; WL-TR-94-1007) Avail: CASI HC A03/MF A01

Operational Flight Programs are the software programs of avionics embedded computer systems. Not only is it desirable to be able to test and model Operational Flight Programs, it is essential. The consequences of not performing accurate Operational Flight Program testing can be devastating. Some of these include premature weapon releases, erroneous flight instrument displays, and complete system failure. In order to test Operational Flight Programs, there are several things one must know about the Operational Flight Program, its weapon system host, its support environment, and how to generate and perform its test. This paper will address these issues as it develops a strategy to test an Operational Flight Program. DTIC

UNMANNED AIR VEHICLE/REMOTELY PILOTED VEHICLE ANALYSIS FOR LETHAL UAV/RPV M.S. Thesis
Burke R. Kaltenberger Sep. 1993 83 p
(AD-A276052) Avail: CASI HC A05/MF A01

An investigation was conducted to provide a comprehensive evaluation of current unmanned aircraft vehicle/remotely piloted vehicle (UAV/RPV) system and its applicability as a lethal weapon system. Numerous systems were evaluated while concentrating on the Department of Defense's more prominent programs, the Pioneer UAV, vertical takeoff and landing (VTOL) UAV, and BQM-147A (EXDRONE) UAV. Israel has proven time and time again that UAVs/RPVs, when properly integrated into the combat arena as a lethal weapon system, can contribute significantly at a lower cost with less risk to an aircrew man in a manned aircraft system. In general the thesis shows many capable UAV/RPV systems designs are available in the market place today. These systems are assessed to determine their viability in the ever changing combat environment. DTIC

DAMAGE TOLERANCE ASPECTS OF A FULL COMPOSITE AIRPLANE FUSELAGE: REQUIREMENTS, MODELLING, PREDICTIONS, EXPERIMENTS
M. N. vanBeijnen, M. J. L. vanTooren, T. deJong, and A. Beukers Jul. 1993 176 p
(LR-728; ETN-94-96138) Avail: CASI HC A09/MF A02

Composite fuselage structures are described, design concepts are mentioned, airworthiness rules for fuselage structures are discussed, and the loads on a fuselage structure and impact characteristics of composite materials are addressed. A theory for strength prediction, based on fracture mechanics and the stress intensity factor, under the presence of cracks is presented. Results of tests on stiffened panels are discussed. A stiffened panel which may improve the damage tolerance capabilities of the given composite sandwich fuselage structure is designed. A stiffened panel is produced and tested to check the predicted residual strength behavior of the panel. ESA

MULTIPLE-SITE DAMAGE IN AIRCRAFT FUSELAGE STRUCTURES
J. Schijve Jul. 1993 29 p
(LR-729; ETN-94-96139) Avail: CASI HC A03/MF A01

Since the Aloha accident, the MSD (Multiple Site Damage) problem of riveted lap joints in aircraft fuselages has drawn much attention. The failure scenarios for a lead crack and more small MSD cracks as discussed by Broek and Swift are summarized, including results of relevant test series of Broek. Small MSD cracks are shown to possibly significantly reduce the load for unstable crack extension. Prevention of catastrophic consequences requires crack arresting capability of the structure. Related aspects of the problem setting are discussed with reference to failure criteria for ligament failure, the MSD problem for existing and new aircraft, and different options for crack stopper bands. Recommendations for future research are made. ESA

MULTIDISCIPLINARY OPTIMIZATION OF HIGH-SPEED CIVIL TRANSPORT CONFIGURATIONS USING VARIABLE-COMPLEXITY MODELING Ph.D. Thesis
Matthew Gerry Hutchison 1993 157 p
Avail: Univ. Microfilms Order No. DA9318184

An approach to aerodynamic configuration optimization is presented for the high speed civil transport (HSCT). Methods to parameterize the wing shape, fuselage shape, and nacelle placement are described. Variable complexity design strategies are used to combine conceptual and preliminary level design approaches, both to preserve interdisciplinary design influences and to reduce computational expense. The preliminary design level analysis methods used to estimate aircraft performance are described. Conceptual design level (approximate) methods are used to estimate aircraft weight, supersonic wave drag and drag due to lift, and landing angle of attack. The methodology is applied to the minimization of the gross weight of an HSCT that flies at Mach 2.4 with a range of 5500 n.mi. Results are presented for wing planform shape optimization and for combined wing and fuselage optimization with nacelle placement. Case studies include both all-metal wings and advanced composite wings. The results indicate the beneficial effect of simultaneous design of an entire configuration over the optimization of the wing alone and illustrate the capability of the optimization procedure. EFFECTS OF FREQUENCY AND AMPLITUDE VARIATIONS OF SUPERIMPOSED MINOR LOADING SEQUENCES ON THE CORROSION FATIGUE BEHAVIOR OF AIRCRAFT STRUCTURAL ALUMINUM ALLOYS Ph.D. Thesis
Andrew Danton Paulson 1993 219 p
Avail: Univ. Microfilms Order No. DA9327339

Economic considerations have forced users of commercial jet transports to retain the services of aircraft that have surpassed the designed lifetime

of structural components of the aircraft. With the increased service time that these aircraft are experiencing, many of the aircraft are becoming increasingly susceptible to corrosive attack. Additionally, the increased public awareness of commercial aircraft incidents has mandated that the behavior of so called 'aging' aircraft structures be better understood. Fatigue crack growth tests were conducted using four aluminum alloys that are commonly used in the structural components of commercial jet transports. Two of these materials represented materials that were commonly used in the construction of the what are now termed 'aging' aircraft. The other two materials are typically used in the new commercial transports. These materials were subjected to trapezoidal loading cycles with superimposed minor loading cycles. The amplitude and frequency of the minor loading cycles were varied in order to determine the effects of such loading variations on the corrosion fatigue behavior of the alloys. It was determined that the minor cycles did not influence the crack growth rate of the material below some specific minor cycle amplitude. Indications were seen that the amplitude at which the minor cycles become active may be influenced by the presence of the corrosive environment. The effect of the active minor cycles on the fatigue crack growth process could be seen in the crack growth rate curves and also in the fractographic analysis of the specimen surfaces. The combined influence of the frequency and environment on the fatigue behavior of the alloys was noted. Once the minor cycles had become active, a lower minor cycle frequency led to a larger impact of the corrosive environment. It is believed that the identification of the activity or inactivity of minor cycle loading will aid in the development of spectrum loading determined from actual components. The actual spectrums may be simplified based on the fact that specific minor cycles are known to be inactive, due to insufficient amplitude to effect the fatigue crack growth process.

(AD-A277100; DOT-VNTSC-FAA-93-8; DOT/FAA/CT-94/10) Avail: CASI HC A08/MF A02

As the fleet of commercial passenger aircraft is utilized beyond their design lives, flaws have developed at the rivet holes of fuselage lap joints on some aircraft which can grow and link up into cracks of significant length. Understanding, predicting, and controlling this crack growth and the ensuing linkup requires analysis and evaluation of the structural parameters in concert with confirmation by testing representative models of the fuselage. A dedicated test facility has been designed, built, and tested for this purpose. Seven full-sized curved fuselage panels have been built and tested. This report describes the design rationale for the facility, the details of its construction and performance and the design and testing of compatible panels which simulate fuselage structural details. Data on basic material properties of interest to the aging aircraft issue have been compiled from existing Literature and from R-curve testing and rivet stiffness testing performed as part of the effort. Analytic techniques have been developed to evaluate stress distributions and to estimate elastic stress intensity factors for flat and curved test panels. A flat test panel has been designed that demonstrates hoop stress equivalence to the curved fuselage. A 3-D FE mesh of a riveted lap joint is also presented. DTIC

V-22: DUAL-USE TECHNOLOGY OR RED HERRING? Research Report, Aug. 1993
William H. Round Apr. 1993 43 p
(AD-A276577; NDU-ICAF-93-F39) Avail: CASI HC A03/MF A01

The V-22 Osprey has been a pawn in the battle between requirements and costs almost from its inception. The major factors with regard to the future of the V-22 are a combination of economic, political and military considerations. It is well known that a coalition of industry, congress and covertly the Marine Corps are on one side of the argument facing the administration and the Office of the Secretary of Defense (OSD) on the other. Each side has invoked arguments either for or against the program in the areas of economics (cost) and utilization (need) requirements.

AIRCRAFT WEIGHT PREDICTION CAPABILITY. VOLUME 1: WEIGHT STUDY AND RESULTS Final Report, 1 Jan. - 30 May 1993
Thomas E. Oole May 1993 65 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277206; ASC-TR-93-5022-Vol-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents the study results, conclusions and recommendation of the application of various weight prediction methodologies to three modern aircraft that are representative of low observable (LO) and/or advanced technologies. In the continuous effort of the Mass Properties Group of the Flight Systems Engineering Division to improve the correlation of predicted weight to actual weight, this report and the corresponding study are intended to serve as a guide to the strength and weaknesses of current available prediction methodologies, identification of technical areas for which methodology is either lacking or inadequate, and recommendations to enhance our capability. Volume 1 of this report documents the background of the study, the weight estimation process of this office, the approach to the study, general results, conclusions, and recommendations to correct deficiencies and improve the Air Force capability. The following volumes will document the methodologies used and the detailed results for the aircraft analyzed. DTIC

ARMY SCOUT/RECONNAISSANCE HELICOPTERS VERSUS UNMANNED AERIAL VEHICLES Report, Aug. 1992 - Apr. 1993
Dennis A. Williamson Apr. 1993 19 p
(AD-A276902; NDU-ICAF-93-S83) Avail: CASI HC A03/MF A01

All armies have long recognized the importance of reconnaissance in the successful accomplishment of their mission. Operations Desert Shield/Storm were no exceptions and, once again, proved that knowing the location of the enemy ground forces is paramount to achieving a decisive victory. However, with the reduction of the defense budget, the U.S. Army needs to relook how best to meet its future aerial scout/reconnaissance requirements. To solve the unarmed reconnaissance deficiency, there is a joint program to develop a new family of unmanned aerial vehicles (UAV's) underway. Likewise, to solve the armed reconnaissance deficiency, the Army is developing a new reconnaissance, attack helicopter. In this paper, I review some of our experiences in the Persian Gulf War with using both UAV's and helicopters. Also discussed are some of the costs associated with each system and its organizational structure. In addition, I outline the major advantages and disadvantages related to the systems. Finally, I provide recommendations on how the Army can best accomplish its reconnaissance mission with these two new systems. DTIC

TECHNICAL EVALUATION OF THE UH-60Q: MEDICAL OXYGEN SYSTEM
James E. Bruckart and Joseph R. Licina Jan. 1994 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276983; USAARL-94-9) Avail: CASI HC A03

The UH-60Q prototype MEDEVAC Black Hawk is configured to provide day/night, adverse weather, emergency movement of patients. The objective of this report is to describe the results of performance tests on the medical oxygen system installed on the prototype aircraft. The medical oxygen system in the aircraft consists of a molecular sieve oxygen generating system (MSOGS) and support equipment. The MSOGS uses bleed air to produce high concentration oxygen. The MSOGS in the prototype aircraft is capable of producing 15 to 20 lpm of 94% oxygen and storing 163 l of oxygen in the backup oxygen supply (BOS). Lower bleed air pressures in ground tests may account for some decrement in performance of the MSOGS when compared to laboratory testing. Inflight testing is required. The support equipment, including oxygen concentration analyzer, BOS pressure monitor, and oxygen flowmeter do not function properly. The regulated oxygen pressure is too low to allow proper operation of the oxygen flow selectors. The oxygen analyzer is redundant and can be eliminated; the flowmeter could be eliminated if the oxygen flow selectors function properly. DTIC

SIX DEGREE OF FREEDOM FLIGHT DYNAMIC MODEL OF A Mk-82 STORE
M. A. Shilo Jan. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277065; ARL-TN-25; DODA-AR-006-666) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A six degree of freedom, flight dynamic model incorporating an aerodynamic database derived from DSTO wind tunnel data was developed for the Mk-82 store. The model can be linked with aircraft flight dynamic models, and it forms part of a general program to model aircraft carriage and delivery, weapon release, and store ballistics. A rudimentary ejection model was also incorporated to represent the forces and moments experienced by the store at the point of release. The model is valid for free stream flight only, and ignores the effects of aircraft-store interaction. DTIC

IMPROVED RESEALING PROCEDURES FOR THE SECOND DESEAL/RESEAL PROGRAM IN RAAF F111 AIRCRAFT FUEL TANKS
S. Batten, R. H. Huang, and L. V. Wake Jan. 1994 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277069; MRL-TR-93-64; DODA-AR-008-616) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A high temperature-resistant polyester sealant was originally employed to seal faying surface grooves in F-111 fuselage fuel tanks as well as structural voids and aerodynamic surfaces. Chemical hydrolysis of this material was detected in March 1974 and led to its replacement by a polysulfide sealant in the late 70's and early 80's. Where possible, the polyester was removed, however much of it remained inaccessibly located between the overlapping panels. It was found that the continued hydrolysis of this residual polyester generated sufficient pressure to penetrate the polysulfide sealant resulting in fuel leaks as well as appearing externally in trails along the skin of the aircraft. To protect the polysulfide from penetration, a mechanical barrier was applied in the form of a layer of epoxy polyamide between the polysulfide and the polyester. This system was successful for some years, however the occurrence of fuel leaks had become unacceptable by 1987. All F-111 aircraft suffered numerous fuel leaks over the period 1988-91 including a number of safety-of-flight (SOF) incidents. A detailed investigation was therefore requested to identify the cause(s) of sealant failures. This investigation found that the sealant and the underlying epoxy barrier coating could be manually peeled from the painted tank surface when prepared by the recommended methods and that two procedures were responsible for the poor adhesion. One of the procedures involved application of the barrier coating over incomplete cure priming paint resulting in solvent attack of the barrier. The second procedure, involving the use of a so-called titanate adhesion promoter, significantly reduced peel strength of the barrier coating to the paint. DTIC

DUAL-BAND INFRARED IMAGING TO DETECT CORROSION DAMAGE WITHIN AIRFRAMES AND CONCRETE STRUCTURES
N. K. DelGrande and P. F. Durbin Jan. 1994 10 p Presented at the 16th SPIE Thermosense: International Conference on Thermal Sensing and Imaging and Diagnostic Applications, Orlando, FL, 4-8 Apr. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-006047; UCRL-JC-115950; CONF-940483-1) Avail: CASI HC A02

We are developing dual-band infrared (DBIR) imaging and detection techniques to inspect air frames and concrete bridge decks for hidden corrosion damage. Using selective DBIR image ratios, we enhanced surface temperature contrast and removed surface emissivity noise associated with clutter. Our surface temperature maps depicted defect sites, which heat and cool at different rates than their surroundings. Our emissivity-ratio maps tagged and removed the masking effects of surface clutter. For airframe inspections, we used time-resolved DBIR temperature, emissivity-ratio, and composite thermal inertia maps to locate corrosion-thinning effects within a flash-heated Boeing 737 airframe. Emissivity-ratio maps tagged and removed clutter sites from uneven paint, dirt, and surface markers. Temperature and thermal inertia maps characterized defect sites, types, sizes, thicknesses, thermal properties and material-loss effects from air frame corrosion. For concrete inspections, we mapped DBIR temperature and emissivity-ratio patterns to better interpret surrogate delamination sites within naturally-heated, concrete slabs and remove the clutter mask from sand pile-up, grease stains, rocks, and other surface objects. DESIGN AND MONTE CARLO ANALYSIS OF AN UNMANNED AERIAL VEHICLE M.S. Thesis
Joseph P. Fordham Dec. 1993 88 p
(AD-A277648) Avail: CASI HC A05/MF A01

In the last several years, software innovations and the increasing speed and availability of microcomputers and workstations have made the dynamic simulation of complex systems more practical. One such system, a short-range Unmanned Aerial Vehicle called Bluebird, was previously modeled on Simulink, a commercial software package. The high fidelity model includes six degree of freedom nonlinear equations of motion with onboard sensors and a Global Positioning System and inertial navigation system. Because of interest expressed by the Unmanned Aerial Vehicle Joint Program Office in how accurately a UAV could identify a target's geographical coordinates, the Bluebird model, with an added guidance and control system, was evaluated as to its navigational and attitudinal accuracy in a dynamic simulation using Monte Carlo techniques. Because of the modular nature of the simulation, future evaluations of manned or unmanned aircraft and avionics will involve relatively uncomplicated changes to the existing model. DTIC

RESPONSE OF A CANTILEVERED PLATE IN SUPERSONIC FLOW Interim Report, Jan. 1993 - Feb. 1994
Mark A. Hopkins Feb. 1994 54 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2401)
(AD-A277487; WL-TM-94-3031) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The response of a thin rectangular panel to supersonic flow over its upper surface is investigated. The panel is fabricated of an isotropic material and has a constant thickness. The panel is fixed along one side such that the flow passes over its freely supported leading and trailing edges parallel to the fixed edge. A Rayleigh-Ritz method is applied to determine the in-plane and transverse response of the panel. The panel deflections either decay to a zero equilibrium or grow to a limited amplitude oscillation once the transients have decayed depending on the panel and flow parameters.

At some combination of panel and flow parameters, the panel will begin to oscillate harmonically about a buckled state. Further increasing the flow conditions will cause the panel to either oscillate periodically about a buckled state or nonperiodically. The steady state response is dependent on the flow conditions and the initial deflections and velocity profiles of the panel. The flow Mach number and panel length-to-width ratios were varied. The cantilevered panel response is compared to previous research. A simply supported panel is briefly discussed and its response is also compared to previous work. DTIC

THE NATIONAL AEROSPACE PLANE (NASP): DEVELOPMENT ISSUES FOR THE FOLLOW-ON VEHICLE
B. W. Augenstein and E. D. Harris 1993 47 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278417; R-3878/1-AF; ISBN-0-8330-1842-4) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This executive summary presents the final results of a project Air Force study on development issues for follow on systems for the National Aerospace Plane (NASP). It provides an independent overview assessment of the NASP program, which is currently in phase 2 of a three-phase research, development, test, and evaluation (RDT&E) program. The project was to aid the NASP Joint Program Office (JPO) and others directly concerned with NASP in two major areas: to assist in efforts to define and validate the utility of potential missions in support of the phase 3 decision milestone and to conduct an integrated system overview of NASP and NASP-derived systems that considers enabling technologies, logistic support, military missions, economics, and political implications. TECHNOLOGIES FOR AVIONICS EMBEDDED COMPUTER SYSTEMS Final Report, period ending 17 Feb. 1993
Charles P. Satterthwaite Feb. 1994 15 p
(AF Proj. 9994)
(AD-A276364; WL-TR-94-1010) Avail: CASI HC A03/MF A01

Avionics embedded computer systems are an important part of the United States Air Force's plans for using advanced technologies to keep their aircraft highly capable and superior. Highly desirable features such as reconfigurability, rapid turnaround, expandability, and testability are made increasingly available through the use of these embedded systems. This paper discusses avionics embedded computer systems primarily through a discussion of their Operational Flight Programs (OFP's), near and far term requirements of OFP maintainers, and current technologies being developed for OFP maintenance. ANALYSIS OF THE EFFECT OF ROUTING STRATEGIES FOR PARALLEL IMPLEMENTATIONS OF A SELECTED AVIONICS APPLICATION Interim Report, 1 Feb. 1992 - 1 Sep. 1993
Jason L. Carter and Stephen L. Hary Dec. 1993 72 p
(AF Proj. 2003)
(AD-A276069; WL-TR-93-1173) Avail: CASI HC A04/MF A01

The purpose of this study is to evaluate the Texas Instruments TMS32OC40 (C40) digital signal processor for a selected avionics application. In this effort, the C40's on-chip communication ports are benchmarked to give indications of the amount of overhead involved in initiating a message transfer and the data throughput rates of the network. A network of C40's is compared to an iwarp parallel processor to compare the processing capabilities between the C40's store-and-forward router and the iWarp's wormhole router. Several network topologies that can easily be constructed from C40's are described, along with ways of partitioning an image processing task across each of them. Performance measurements of both the C40's and iWarp's performance on parallelized implementations of the image processing algorithm are detailed, along with estimated measurements for large-scale arrays of C40's. Finally, the C40's computing power is compared with an avionics hardware program being developed at wright Laboratories, System Avionics Division, Information Processing Technology Branch. DTIC

STUDY OF VIRTUAL PROTOTYPING OF AIRCRAFT INSTRUMENTS Concluding Report
Peter M. Wells, R. D. Kobierski, and Gordon Youngson 9 Aug. 1993 204 p
(CMC-0687-1090; DSIS-94-01381; CTN-94-61215) Copyright Avail: CASI HC A10/MF A03

A project was initiated to identify the methodology, cost parameters, and data structure required to create a taxonomy of Canadian Forces aircraft cockpit representations using the Virtual Applications Prototyping System (VAPS). The cockpit panels of the CC-130H Hercules were selected for prototyping as they provide a convenient and timely test case for this process. During the data collection process required to support generation of the VAPS prototypes, a number of lessons were learned regarding both aircraft cockpit preparation and photographic techniques. A VAPS prototype library has been designed which utilizes the capacity of VAPS to create composite prototypes by loading reference components from other files. This effort resulted in generation of significantly more complex VAPS prototypes than those previously used. The variety of options used to improve performance, including hardware and software based approaches, are discussed. A VAPS component inventory database was created for systematic organization of information on components of VAPS prototypes. Efforts were made to establish links between the VAPS and other applications, and to develop software tools to enable the VAPS prototype library to support systems engineering tasks. A low-cost cockpit demonstration system that would maximize the utility of VAPS prototypes is also proposed. Author (CISTI)

AEROSPACE SOFTWARE ENGINEERING FOR ADVANCED SYSTEMS ARCHITECTURES
Nov. 1993 248 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277101; AGARD-CP-545) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

During the past decade, many avionics functions which have traditionally been accomplished with analog hardware technology are now being accomplished by software residing in digital computers. Indeed, it is clear that in future avionics systems, most of the functionality of an avionics system will reside in software. In order to design, test, and maintain this software, software development/support environments will be extensively used. The significance of this transition to software is manifested in the fact that 50 percent or more of the cost of acquiring and maintaining advanced weapons systems is directly related to software considerations. It is also significant that this dependence on software provides an unprecedented flexibility to quickly adapt avionics systems to changing threat and mission requirements. Because of the crucial importance of software to military weapons systems, all NATO countries are devoting more research and development funds to explore every aspect of software science and practice. The purpose of this symposium was to bring together military aerospace software experts from all NATO countries to share the results of their software research and development and virtually every aspect of software was considered with the following representing a partial set of topics: aerospace electronics software specification, software design, programming practices and techniques, software validation and testing, software management, and software environments. ASSESSMENT OF INTERIOR MODIFICATIONS IN C-130 AND C-141 AIRCRAFT FOR NIGHT VISION GOGGLE OPERATIONS Final Report, Mar. - Dec. 1992
Jeffrey L. Craig May 1993 20 p
(Contract F33615-89-C-0532)
(AD-A276843; AL/CF-TR-1993-0095) Avail: CASI HC A03/MF A01

An evaluation was conducted to examine the effects of interior paint scheme modifications to C-130 and C-141 aircraft on night vision goggle (NVG) operations. The evaluation consisted of direct measurement of aircraft interior radiance levels, calculation of surface reflectivities, and a human factors assessment of effects on aircrew NVG performance. The data were collected for both modified and original interior scheme C-130 and C-141 aircraft at Pope AFB and Charleston AFB, respectively. Reflectance values were determined for various flight deck and cargo bay surfaces. The reflectance values were calculated from the radiance levels within the sensitivity range of the NVG's. The results indicated that the reflectances were higher in modified aircraft for the majority of surfaces measured, but well within the specifications set by the relevant military standard. The human factors evaluation indicated that the vast majority of aircrew responding experienced no adverse effect on NVG performance attributable to the new interior scheme. In general, it was concluded that the modified interior scheme should not interfere with NVG operations. DTIC

(AF Proj. 9994)
(AD-A276846; WL-TR-94-1033) Avail: CASI HC A03/MF A01

Developing reusable software for avionics systems is a challenge to software engineers. The task involves foreseeing future applications, modeling real-world events, using appropriate CASE tools throughout the development life cycle, and providing for storage and retrieval of reusable software components. This report presents a model for developing and managing reusable software components, briefly describes the software process maturity model and the integration of CASE tools with the process maturity model. It also identifies tools/techniques and methodologies for real-time systems development, examines the critical issues in managing software projects, and offers the management a set of guidelines to introduce software engineering methodologies and CASE tools within the organization through a model project which may enforce standards for new projects. SYNTHETIC VISION TECHNOLOGY DEMONSTRATION. VOLUME 1: EXECUTIVE SUMMARY Final Report
Malcolm A. Burgess, Terence Chang, Dale E. Dunford, Roger H. Hoh, Walter F. Horne, and Richard F. Tucker Dec. 1993 111 p
(DOT/FAA/RD-93/40-Vol-1) Avail: CASI HC A06/MF A02

This report contains the description and results of a Synthetic Vision technology demonstration program conducted jointly by the Federal Aviation Administration, the Department of Defense and industry. The relevant technologies including millimeter wave radar sensors, infrared sensors, head-up displays, and computer processing were developed and tested in static tower tests and in flight tests in which the weather conditions were carefully measured and documented. The purpose of the program was to evaluate and demonstrate the performance of the imaging sensors and of the complete imaging system during aircraft approaches and landings in low-visibility conditions. The static tower test facility used was the Avionics Tower Test Facility, located at Wright Patterson AFB, in which candidate sensors were set up at approximately 260 feet overlooking a nearby runway. The runway scene imaged by the sensors was instrumented to carefully measure the characteristics of fog, rain and snow as those conditions occurred in 1991-1992. Sensor performance and phenomenology was then fully characterized to provide a basis for further sensor development and for selection of sensors with which to proceed to flight test. The test aircraft used was a Gulfstream II configured with a comprehensive data collection system and instrumentation to permit measurement of fog and precipitation through which the aircraft was flown as well as system and pilot performance during those operations. Millimeter wave sensors and an infrared sensor were used to provide an electronic image of the runway on both head-up and head-down displays during approach, landing and takeoff. Test and demonstration flights were flown into 27 different airports in a wide variety of rain, fog and snow conditions during the period of May through December, 1992. This first volume is an executive summary containing an overview of the work from a management perspective. Author

This report contains the description and results of a Synthetic Vision technology demonstration program conducted jointly by the Federal Aviation Administration, the Department of Defense and industry. The relevant technologies including millimeter wave radar sensors, infrared sensors, head-up displays, and computer processing were developed and tested in static tower tests and in flight tests in which the weather conditions were carefully measured and documented. The purpose of the program was to evaluate and demonstrate the performance of the imaging sensors and of the complete imaging system during aircraft approaches and landings in low-visibility conditions. The static tower test facility used was the Avionics Tower Test Facility, located at Wright Patterson AFB, in which candidate sensors were set up at approximately 260 feet overlooking a nearby runway. The runway scene imaged by the sensors was instrumented to carefully measure the characteristics of fog, rain and snow as those conditions occurred in 1991-1992. Sensor performance and phenomenology was then fully characterized to provide a basis for further sensor development and for selection of sensors with which to proceed to flight test. The test aircraft used was a Gulfstream II configured with a comprehensive data collection system and instrumentation to permit measurement of fog and precipitation through which the aircraft was flown as well as system and pilot performance during those operations. COCKPIT ELECTRONIC DISPLAY WORKSHOP: A SYNOPSIS Final Report, Apr. - Oct. 1993

M. S. Huntley, Jr. and Rowena Morrison Dec. 1993 25 p Workshop held in Cambridge, MA, 7-9 Apr. 1993

(AD-A277728; DOT-VNTSC-FAA-93-21; DOT/FAA/RD-93/42) Avail: CASI HC A03/MF A01

Thirty-six government, academic, and industry human factors professionals participated in a workship convened at the Volpe National Transportation Systems Center to identify human factors issues associated with depicting terminal area operations information on electronic cockpit displays. Two working groups, formed from the meeting attendees, identified a variety of research issues associated with the identification, distribution, and electronic presentation of terminal area information to flight crews. This document presents a summary of the proceedings produced by that meeting and an edited list of research issues derived from those proceedings. The summary document also includes two disks containing the original workshop proceedings. These disks were formatted in Microsoft Word 5.1 for Macintosh. Please refer to the Read me file for further instructions. DTIC

AN ANALYSIS OF NON-INTEGERIZING THE AIRCRAFT ENGINES COST EFFECTIVENESS ANALYSIS SPREADSHEET MODEL (CEAMOD VERSION 2.0) M.S. Thesis

Karl F. Rau Dec. 1993 114 p

(AD-A276251) Avail: CASI HC A06/MF A02

This thesis investigated the effect of integerization in the Cost Effectiveness Analysis Spreadsheet Model (CEAMOD Version 2.0) used by the Navy and the Air Force for decision-making in their aircraft engine Component Improvement Programs (CIP). A non-integerized model was developed and sensitivity analysis was performed to determine the cost drivers of the revised model. Three major cost drivers were then utilized as sensitivity analysis tools for comparing the decision values obtained from the current model with those obtained from the revised model. The author concluded that while the non-integerized CEAMOD is more theoretically correct, it would not lead to different decisions than CEAMOD Version 2.0. DTIC

SOLUTION OF THE AVERAGE-PASSAGE EQUATIONS FOR THE INCOMPRESSIBLE FLOW THROUGH MULTIPLE-BLADE-ROW TURBOMACHINERY

J. J. Dreyer and W. C. Zierke Feb. 1994 125 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00039-92-C-0100)

(AD-A276515; PSU/ARL-TR-94-05) Avail: CASI HC A06

A system of equations governing the incompressible flow through a multiple-blade-row turbomachine is presented. These equations basically form the pseudo-compressible analog to the equations derived by Admaczyk 1984 for compressible, average-passage flow. The methodology behind the derivation is outlined, including a closure model for the time-averaged form of the equations. The equations are then preconditioned to facilitate numerical treatment. An explicit numerical procedure based on Runge-Kutta time stepping for cell-centered, hexahedral finite volumes is outlined for the approximate solution of the governing equations. Convergence

acceleration techniques, boundary conditions, and closure issues are also addressed for the numerical scheme. Finally, results are presented for a simulation of the high Reynolds number flow through a two-blade-row, axial-flow pump. These comparisons suggest that the pseudo-compressible average-passage equations can make reasonable predictions. DTIC

COMPUTATIONAL PREDICTION OF STALL FLUTTER IN SPANWISE-FINITE BLADE CASCADES Ph.D. Thesis
Tsong-Hsin Chen 1993 160 p
Avail: Univ. Microfilms Order No. D/ 9328508

Aeroelastic instabilities in turbomachinery are of great importance in practice and in the design process. Stall flutter is one of the important off-design phenomena at which airfoils experience flow separation with propagating stall cells. Prediction to prevent the onset of stall for given blade geometry and material properties is necessary. In this study, the unsteady aeroelastic behavior of the turbomachinery blade cascades is analyzed. A 'pseudo-three-dimensional' approach based on the well-tested vortex method is employed for the unsteady aerodynamics of spanwise-finite turbomachine blade cascades. The cascaded airfoils are modeled structurally using discretized beam theory and coupled with the unsteady aerodynamics algorithm for simultaneous solution by a time-marching technique. Before performing these computations, the static blade deflections and natural frequencies with/without rotation are all compared with the available experimental and analytical works to ensure the reliability of the structure dynamics algorithm. A six-element blade is proposed in order to reduce the CPU time and yet maintain acceptable accuracy. The mutual interaction of the structural dynamic displacement and the unsteady aerodynamic loading is effectively captured by this algorithm. The pseudo-three-dimensional results for the spanwise-finite airfoil cascades are shown to compare well with those for infinite linear cascades modeled by a two-dimensional characteristic section with a single degree-of-freedom in either bending or torsion. The computational results for a cascade of compressor blades with pretwist show that the bending motion normal to the chord dominates blade displacement for stall flutter in the fundamental frequency mode. The results also indicate that while entrainment or frequency synchronization may occur over a certain interval of frequency, the spanwise behavior of the cascade can exhibit considerable variations. The possibility of the second harmonic of the stall frequency exciting the blade at its natural frequency is uncovered. As to a lower stiffness blade, the torsional motion is found to dominate the whole motion and evoke a similar entrainment response like pure torsional motions in two-dimensional cascades. Finally, the chaotic behavior of nonlinear systems is observed in the aerodynamics of airfoil cascades when a coherent vibration is not present in coupled mode flutter. However, the limit cycle behavior is shown to be present in pure torsional or bending mode flutter. Dissert. Abstr.

DEVELOPMENT OF A CASCADE SIMULATION OF FAN-PASSAGE FLOW M.S. Thesis
Eric A. Tapp Dec. 1993 139 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277234) Avail: CASI HC A07

A small-scale blowdown wind tunnel apparatus was developed to investigate techniques to alleviate the negative effects of shock-boundary layer interaction in the blading of aircraft engine fans. Using shadowgraph and surface injection techniques, probe surveys, and static pressure measurements, it was shown that acceptable periodicity and repeatability could be obtained in a two-passage cascade model at M = 1.4 if air supply pressure, back pressure, and porous-wall bleed pressures were properly controlled. It was also shown that local separation due to shock boundary layer interaction was present at the design flow incidence of 1.15 deg, but not at 0.85 deg. Complete data are reported for the design condition to serve as a baseline for separation alleviation experiments. Necessary hardware and software developments are also documented. DTIC

Performance degradation of multiple-input multiple-output (MIMO) control systems having limited actuators is often handled by augmenting the controller with an antiwindup mechanism, which attempts to maintain system performance when limits are encountered. The goals of this paper are: (1) To develop a method to analyze antiwindup systems to determine precisely what stability and performance degradation is incurred under limited conditions. It is shown that by reformulating limited actuator commands as resulting from multiplicative perturbations to the corresponding controller requests, mu-analysis tools can be utilized to obtain quantitative measures of stability and performance degradation. (2) To propose a linear, time invariant (LTI) criterion on which to base the antiwindup design. These analysis and design methods are illustrated through the evaluation of two competing antiwindup schemes augmenting the controller of a Short Take-Off and Vertical Landing (STOVL) aircraft in transition flight. (AD-A276936) Avail: CASI HC A07

Since the enactment of Title 10, Section 2403 of the United States Code in 1985, written warranty clauses have been mandated for the procurement of all major weapon systems. This thesis discusses the aircraft engine warranty program established by the Naval Air Systems Command in response to that warranty legislation. Warranty procedures and issues are examined during procurement, contract negotiations, and in the daily operations of the fleet. The aircraft engine warranty program of a major commercial airline (United Airlines) is presented to allow the reader to form a basis from which to make program comparisons. Those areas in which a commercial warranty may be applicable to a military environment are described and analyzed. Conclusions are drawn concerning the effectiveness of the Navy's warranty program and recommendations are suggested for improvements and/or follow on studies. DTIC

IN FLIGHT MEASUREMENT OF STEADY AND UNSTEADY BLADE SURFACE PRESSURE OF A SINGLE ROTATION LARGE SCALE ADVANCED PROP-FAN INSTALLED ON THE PTA AIRCRAFT Final Report
D. Parzych, L. Boyd, W. Meissner, and A. Wyrostek Sep. 1991 188 p Original contains color illustrations
(Contract NAS3-23051; RTOP 535-03-10)
(NASA-CR-187096; NAS 1.26:187096) Avail: CASI HC A09/MF A02; 42 functional color pages

An experiment was performed by Hamilton Standard, Division of United Technologies Corporation, under contract by LeRC, to measure the blade surface pressure of a large scale, 8 blade model prop-fan in flight. The test bed was the Gulfstream 2 Prop-Fan Test Assessment (PTA) aircraft. The objective of the test was to measure the steady and periodic blade surface pressure resulting from three different Prop-Fan air inflow angles at various takeoff and cruise conditions. The inflow angles were obtained by varying the nacelle tilt angles, which ranged from -3 to +2 degrees. A range of power loadings, tip speeds, and altitudes were tested at each nacelle tilt angle over the flight Mach number range of 0.30 to 0.80. Unsteady blade pressure data tabulated as Fourier coefficients for the first 35 harmonics of shaft rotational frequency and the steady (non-varying) pressure component are presented. Author

INLET DISTORTION IN ENGINES ON VSTOL AIRCRAFT Final Technical Report, Oct. 1989 - Dec. 1993
Choon S. Tan and Edward M. Greitzer May 1994 61 p
(Grant NAG3-1567)
(NASA-CR-195841; NAS 1.26:195841) Avail: CASI HC A04/MF A01

This report presents the results of a research program on inlet distortion in engines on VSTOL aircraft carried out at the MIT Gas Turbine Laboratory

during the period Oct. 1989 - Dec. 1993. The program focused on the development of three dimensional flow computational methodology for predicting the effects of nonuniform flow on the performance of aircraft engines in VSTOL aircraft, the development of a three dimensional instability analysis of flow in multistage axial compressors, and the preliminary applications of these newly developed methodologies for elucidating the effects of flow three dimensionality. The accomplishments of the program are brought out when the current status of predictive capabilities for three dimensional flow instabilities in compressors is assessed against that in 1989. A USER'S MANUAL FOR THE COST EFFECTIVENESS ANALYSIS SPREADSHEET MODEL FOR AIRCRAFT ENGINES (CEAMOD VERSION 2.0) M.S. Thesis
Ross R. Reeves Dec. 1993 364 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278042) Avail: CASI HC A16

This thesis provides a comprehensive procedures manual and user's guide which will enable both current users and beginners to understand and employ Version 2.0 of the Cost Effectiveness Analysis model (CEAMOD), which is written in EXCEL spreadsheet software, in their service's aircraft engine Component Improvement Programs (CIP). The purpose of the CEAMOD is to project the possible savings which would be achieved from an Engineering Change Proposal's (ECP) implementation. The thesis begins by describing the model's background, basic assumptions, and format. Next, a detailed description of each page and the cell formulas used in each column of the spreadsheet are provided. A 'getting started' user's guide was also created to provide the user with the basic information necessary to actually use the CEA Deck/EXCEL spreadsheet software. An example of each page of the CEA model is provided as well as the Standard History File fleet input pages. DTIC

ANALYSIS OF INTERMEDIATE LEVEL MAINTENANCE FOLLOWING F404-GE-400 ENGINE COMPONENT LIFE REDUCTIONS M.S. Thesis
Jeri S. King and William M. Tooker Dec. 1993 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277918) Avail: CASI HC A05

This thesis is an analysis of the effect that component life limit reductions of the F404-GE-400 engine have on AIMD Lemoore Power Plants Division operations. Estimations of fleet impact due to F404 component life limit reductions did not include the affect on production work centers. This thesis used simulation modeling of the F404 engine repair process at AIMD Lemoore to investigate the impact of these reductions. The simulation model outcomes provide strong indications that AIMD Power Plants Division operations will not be substantially altered by F404 component life limit reductions. However, there will be a significant impact on engine turn around time and the number of aircraft grounded awaiting engines. Recommendations to reduce the impact of component life limit reductions include improved logistical support in long-lead repair items. Additionally, the researchers recommend greater use of simulation modeling in future planning and analysis of significant logistics support changes. DTIC

CONTROLS DESIGN WITH CROSSFEEDS FOR HOVERING ROTORCRAFT USING QUANTITATIVE FEEDBACK THEORY
Semiannual Progress Report, Nov. 1993 - Mar. 1994
Daniel J. Biezad 15 Apr. 1994 30 p
(Contract NCC2-833)
(NASA-CR-195765; NAS 1.26:195765) Avail: CASI HC A03/MF A01

This work is extending the research accomplished on project NCC2-751. A newly implemented helicopter model has been used to simulate 25 flight configurations near hover for the UH-60 RASCAL aircraft. A new engine model has been installed in the FORECAST simulation (alias UMGENHEL) for the better prediction of the yaw and heave responses. By applying the decoupling metric from project NCC 751 it was determined that the aileron to pitch and the elevator to yaw responses do not indicate the need for crossfeeds since both of them have a decoupling metric value over 20 dB (less than 10 percent coupling). In the case of the aileron to heave and the elevator to heave responses, the large size and the overlapping of the templates indicate that a low-order dynamic crossfeed cannot be found. The low-order dynamic crossfeed selection is proceeding, however, for the remaining eight crossfeeds. Note that most of them have successfully decoupled the system by 20 dB or more, except for the rudder to heave crossfeed (18.2 dB). It is probable that the engine model needs more accuracy to further improve the heave to yaw crossfeed decoupling metric value. To see how the new low-order dynamic crossfeeds perform, a simulation was accomplished using MATLAB SIMULINK. Author (revised)

AEROELASTIC VIBRATIONS OF LIFTING SURFACES Ph.D. Thesis [VIBRATIONS AEROELASTIQUES DES SURFACES PORTANTES]
Cosmas PanditPagwiwoko 1991 159 p In FRENCH
(ECL-91-01; ETN-94-95985) Avail: CASI HC A08/MF A02

Work to establish calculation methods for solving aeroelastic problems is presented. The software developed is listed, and calculations were carried out for a hypothetical missile. A calculation method for unsteady aerodynamic loads in the subsonic and supersonic regimes modeling the lifting surface by singularities is presented. The problem of aeroservoelasticity is addressed. Flutter forces are presented in the form of a V-g diagram and by the place of the dynamic system transfer function roots. Aeroelastic responses of the nonlinear system and the control system are observed in the time domain. During numerical simulation, the gust effect and noise in the aeroelastic behavior are taken into account. ESA

A helicopter response type is a description of the coupling between the cockpit controls and the flight characteristics of the helicopter. A helicopter can be used to perform several different tasks, each requiring a different response type. During a given mission, it may be necessary to execute several tasks and therefore there is a requirement to be able to change the control configuration, or to reconfigure the control, while in flight. A study was conducted to examine the possibility of switching between configurations during flight and to determine the best way to achieve a control transition. An automatic control system was implemented on a helicopter simulator and a set of control algorithms was obtained which implemented seven response types. Most of these algorithms used proportional feedback. Two attempts were made to develop a control reconfiguration strategy. It was found that the most critical factor is the minimization of a control discontinuity over a transition. A method was developed to achieve such a minimization by setting the reference or

initial control deflection equal to the current or final control deflection of the old configuration. The tests performed on the reconfiguration algorithms show that smooth transitions are achievable between all response types in the appropriate channels. CISTI

TECHNICAL EVALUATION OF THE UH-60Q: AIRCRAFT IN TYPICAL AEROMEDICAL EVACUATION MISSIONS
James E. Bruckart and Joseph R. Licina Feb. 1994 37 p
(AD-A276944; USAARL-94-10) Avail: CASI HC A03/MF A01

The UH-60Q prototype MEDEVAC Black Hawk is configured to provide day/night, adverse weather, emergency movement of patients. The objective of this report is to describe the ability of the prototype aircraft to perform typical aeromedical evacuation missions. The prototype aircraft performed five simulated day and night medical evacuation missions as described in the Materiel Need Statement for the Dustoff UH-60Q. Medical aidmen and aviators rated the medical interior and avionics systems and provided comments on their in-flight experiences. The prototype UH-60Q Black Hawk is capable of performing the typical MEDEVAC missions. Nondevelopmental components of the medical interior require some refinements including improved vertical clearance for litters, improved durability, and environmental tolerance. Communications and cabin lighting require additional study to refine these requirements. DTIC

ACTIVE CONTROL FOR FIN BUFFET ALLEVIATION Final Report, Jun. 1992 - Jun. 1993
Holt Ashley, Stephen M. Rock, Ramarao Digumarthi, Kenneth Chaney, and Alfred J. Eggers, Jr. Jan. 1994 142 p
(Contract F33615-92-C-3605)
(AD-A276844; WL-TR-93-3099) Avail: CASI HC A07/MF A02

A one year program of research for fighter aircraft with twin vertical stabilizers and which operate at high angles of attack was undertaken the following objective: to examine the possibility that active control can alleviate the response to buffeting and enhance fatigue life of the structure. Although there is no way that the phenomenon could have been anticipated during the initial phases of their design, 'fin buffeting' as a consequence of high-alpha maneuvers has been encountered on several military aircraft with such twin tails. Other affected fighters include the F-14 and the F/A-18. Future designs for which some level of buffeting is anticipated are the F-22. Measurements on a wind-tunnel model have already reported fin buffeting. Although they have single, center-line, vertical stabilizers, similar phenomena have occurred at high alpha on the X-29 and the X-31. DTIC

NUMERICAL ANALYSIS OF TRANSONIC WING BUFFET Ph.D. Thesis
Shen-Jwu Su 1992 151 p
Avail: Univ. Microfilms Order No. DA9318138

Transonic wing buffet is caused by shock-induced boundary layer separation on the wing. The inherent fluctuating buffet force can significantly reduce the flight performance of an airplane. An analysis of transonic wing buffet phenomena using modern numerical techniques is described here. The numerical tool developed for this purpose can accurately compute the solution for turbulent flow over a wing at high Reynolds numbers and at fairly high angles of attack. The computer code consists of two major parts: a three dimensional multiple block grid generation package, and an implicit finite difference code for solving the thin-layer compressible Navier-Stokes equations. Wind tunnel data for transonic flow past a swept ONERA M6 wing were used for code validation. The computed pressure distributions compared favorably with measurements. The buffet boundaries were predicted for the M6 wing, and the corresponding shock boundary-layer interaction during buffet onset was described. In order to avoid the separation penalties and to raise the buffet boundaries in the transonic speed regime, two types of wing designs, namely the twisted wing and step wing concepts, have been studied here. They were implemented separately by modifying the M6 wing geometry. The results indicate that both types of wing modifications can significantly alter the shock-wave and boundary-layer characteristics in a favorable way to reduce the rise of shock-induced separation on the wing and thus efficiently raise the buffet onset boundary. To examine the complex separated flow pattern obtained from numerical simulation, the concept of envelope of limiting streamlines and topology of phase plane was discussed. This provides a generalized approach to the classification of three dimensional separated flow patterns defined by streamlines for flow at or away from a solid surface. Dissert. Abstr.

MODELING OF AIRCRAFT UNSTEADY AERODYNAMIC CHARACTERISTICS. PART 1: POSTULATED MODELS
Vladislav Klein (George Washington Univ., Hampton, VA.) and Keith D. Noderer (George Washington Univ., Hampton, VA.) May 1994 26 p
(RTOP 505-64-52-01)
(NASA-TM-109120; NAS 1.15:109120) Avail: CASI HC A03/MF A01

A short theoretical study of aircraft aerodynamic model equations with unsteady effects is presented. The aerodynamic forces and moments are expressed in terms of indicial functions or internal state variables. The first representation leads to aircraft integro-differential equations of motion; the second preserves the state-space form of the model equations. The formulations of unsteady aerodynamics is applied in two examples. The first example deals with a one-degree-of-freedom harmonic motion about one of the aircraft body axes. In the second example, the equations for longitudinal short-period motion are developed. In these examples, only linear aerodynamic terms are considered. The indicial functions are postulated as simple exponentials and the internal state variables are governed by linear, time-invariant, first-order differential equations. It is shown that both approaches to the modeling of unsteady aerodynamics lead to identical models. Author

FAULT DETECTION AND ISOLATION FOR THE BLUEBIRD TEST BED AIRCRAFT M.S. Thesis
Mario J. Levesque Dec. 1993 117 p
(AD-A277979) Avail: CASI HC A06/MF A02

A Fault Detection and Isolation (FDI) algorithm design is presented using the Multiple Model algorithm technique for the Bluebird aircraft being developed at the Naval Postgraduate School. The requirement to maintain high performance in the dynamic system of the aircraft necessitates the use of FDI techniques to detect and isolate malfunctions in the sensors and actuators of the aircraft without using hardware redundancy. The solution presented makes use of analytical redundancy in a bank of Kalman filters. Statistical tests using Bayesian theory are applied on the filter's innovations to perform the task of detection and isolation. The algorithm was developed using MATLAB software from The Math Works, Inc. The work presented in this thesis is related only to the task of FDI. The remaining task of the monitoring system, reconfiguration and continued operation by the observed plant after a failure detection, will not be addressed. DTIC

VARIABLE-RESOLUTION IMAGERY FOR FLIGHT SIMULATION Final Report, Jun. 1989 - Jun. 1993
George A. Geri, Yehoshua Y. Zeevi, and Craig A. Vrana Jan. 1994 100 p
(Contract F33615-90-C-0005)
(AD-A276199; AL/HR-TR-1993-0180) Avail: CASI HC A05/MF A02

A position-varying, low-pass filter was used to produce variable-resolution images whose spatial frequency content varies as a function of distance from their center. Such images can be matched in some sense to the spatial inhomogeneities of the human visual system, and thus, they may be visually acceptable even though they contain less information than an unprocessed version of the same image. Following a discussion of image representation with nonuniform sampling and of the concept of locally bandlimited spaces, two experiments were performed to visually assess variable-resolution images. In Experiment 1, images were generated using a series of distortion functions (differing in central blur, peripheral blur, and blur gradient) chosen to approximate cortical magnification functions

(CMFN's) derived from existing anatomical and psychophysical data. The distortion functions, corresponding to the images that were just discriminable from an unprocessed image, were used to define the wide-field CMFN associated with changes in blur discrimination across the visual field. In Experiment 2, blur thresholds were measured using apertures in the form of either circles or 3 deg-wide angular segments centered in either 15 deg or 30 deg eccentricity. Differences in blur discrimination for the two stimulus configurations, matched in area, suggest that the spatial organization of the visual mechanisms underlying blur discrimination changes with eccentricity. Finally, the perceptual data obtained here were used to efficiently sample and represent a variable-resolution image. DTIC

AIRCRAFT SIMULATION AND PILOT PROFICIENCY: FROM SURROGATE FLYING TOWARDS EFFECTIVE TRAINING

P. G. A. M. Jorna, E. R. A. vanKleef, and W. P. Boer 30 Jul. 1992 32 p Presented at the AGARD Conference on Piloted Simulation Effectiveness, Brussels, Belgium, 1992

(AD-B179300; NLR-TP-91489-U; ETN-94-95973) Avail: CASI HC A03/MF A01

Experiences with the application of simulators in military flight training are reviewed and research strategies like the development of objective performance measures in support of validation trials and future simulator development are reported. It is proposed to prototype simulator concepts before implementing them and relevant research initiatives in this area are reviewed. The credibility of simulators is assessed from a pilot's perspective. It is noted that a missing link between simulator and real flight is the obvious absence of physical danger. Safety serves to reduce anxiety and influences the pilot strategies for task execution: who is afraid of crashing a simulator. Effects of anxiety on performance could be demonstrated and interactions with high workload conditions occurred. Coping with the mental perils of flight is an important component of pilot proficiency and simulating such an environment, or at least its impact on performance, is one of the many challenges for the training community. MODEL BORNE DATA MANAGEMENT SYSTEM FOR WIND TUNNEL TESTING, PHASE 2 Final Report, 1 Oct. 1991 - 1 Oct. 1993

Lee F. Webster and T. S. Paige Nov. 1993 37 p

(Contract F33615-91-C-3007)

(AD-A276296; TESCO-TR-93-1-Phase-2; WL-TR-93-3125-Phase-2) Avail: CASI HC A03/MF A01

This report covers the development of a modern model mounted wind tunnel data acquisition and processing system called MDARS, short for Modular Data Acquisition and Recording System. During this Phase, prototypes of the model borne components and the pc interface were developed. The system was then installed in a HP-MaRV model for demonstration testing in AEDC's wind tunnel B. Following these tests the performance and durability of the system was analyzed and lessons learned were identified and incorporated into a production version of the system. These activities resulted in a proven data system, ready for marketing. The MDARS uses modern high density surface mount components in a compact modular/bus arrangement which allows a size which can be accommodated by most wind tunnel models. It also allows the system to be controlled and data to be acquired by a modern personal computer thus decreasing or eliminating dependence on facility data systems. The system multiplexes all data channels and converts all analog signals digital. The remote system communicates with the Control Personal Computer by fiber optic cable. The use of MDARS will reduce facility data system dependence while reducing test set up costs and schedule delays. DTIC

HYPERVELOCITY TUNNEL 9 MACH 10/14 CALIBRATION

Dan Marren 31 Jan. 1994 65 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A275960; NSWCDD/TR-92/160) Avail: CASI HC A04

This report documents the Tunnel 9 Mach 10/14 Calibration test program (WTR 1608) performed at the Naval Surface Warfare Center, White Oak, Maryland. This effort was sponsored by the National Aerospace Plane Joint Program Office (NASP JPO). Free stream flow field parameter distributions were obtained for both the Mach 10 and 14 nozzles spanning the Reynolds number range. A total of four Mach 10, and ten Mach 14 runs were performed during this test program. The test period was 7 to 22 May 1991. Results from this test entry were combined with previous test data in the final analysis. Data from the test reveal that high quality uniform flow exists and that deviations in core flow field parameters are comparable with the calibration data taken in the past. DTIC

CLEANROOM ENGINEERING HANDBOOK. VOLUME 6: CERTIFICATION TEAM PRACTICES

31 Jul. 1993 54 p

(Contract F19628-88-D-0032)

(AD-A275951) Avail: CASI HC A04/MF A01

This is one of a series of six engineering handbooks prepared for and used by the engineering staff at Picatinny Arsenal for the STARS technology transfer demonstration. The handbooks define the engineering process and algorithms that will be used in Cleanroom projects. They are designed to provide support to trained engineers using Cleanroom engineering, not to substitute for training. This volume describes the activities of Cleanroom software certification for each increment/accumulation of project development. Process P5.j.2, preparation for certification of accumulation j, and process P6.j, software certification for accumulation j, are expanded into engineering subprocesses (i.e., tasks) for execution by Cleanroom-trained software engineers. These tasks result in the preparation for and performance of the certification of developed software. DTIC

CLEANROOM ENGINEERING HANDBOOK. VOLUME 1: CLEANROOM ENGINEERING PROCESS INTRODUCTION AND OVERVIEW

31 Jul. 1993 46 p

(Contract F19628-88-D-0032)

(AD-A275949) Avail: CASI HC A03/MF A01

This is one of a series of six engineering handbooks prepared for and used by the engineering staff at Picatinny Arsenal for the STARS technology transfer demonstration. The handbooks define the engineering process and algorithms that will be used in Cleanroom projects. They are designed to provide support to trained engineers using Cleanroom Engineering, not to substitute for training. This handbook, Volume 1, presents an introduction to the Cleanroom engineering process model and is recommended for all software planning and development participants. It defines the Cleanroom process in light of the project organization which consists of: The Specification Team; The Development Team; The Certification Team; and the software transformations which are: Specification Development - To define the software system to be developed and record the definition in the specification document; and Software Development and Certification - To develop and certify software in the target language that runs on the target processor and exhibits the same behavior described in the specification. DETERMINING THE BEARING CAPACITY OF FLEXIBLE AIRFIELD PAVEMENTS USING A HEAVY WEIGHT DEFLECTOMETER M.S. Thesis

R. E. Fenton Sep. 1992 173 p

(ISBN-0-315-86210-6; CTN-94-61186) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

In 1985, increasing costs and the inconvenience associated with conducting plate bearing tests prompted Transport Canada to investigate the feasibility of replacing the controlled rate of loading (CROL) test with falling weight deflectometer testing for determining the standard surface bearing strength Pstd of flexible airfield pavements. In summer 1990, 180 heavy weight deflectometer (HWD) and CROL tests were conducted at eight Transport Canada airfields in central Canada. The Pstd determined from the CROL test, Pcrol, was compared to the HWD deflection at the center of the HWD loading plate, the radius of curvature of the HWD deflection bowl, and the area of the HWD deflection bowl at loads of 60, 120, 180, and 240 kilonewtons. A relationship between the slope and intercept of the deflection bowl area versus HWD load plots and Pcrol with a correlation coefficient of about 0.84 was developed. This relationship is considered to be a viable method of estimating the Pstd from HWD data for airfields located in central Canada. Author (CISTI)

DEVELOPMENT OF A ROBOTIC SIMULATOR FOR STUDYING INTERFERENCE AND CONTACT PROBLEMS M.S. Thesis [DEVELOPPEMENT D'UN SIMULATEUR ROBOTIQUE POUR L'ETUDE DES PROBLEMES D'INTERFERENCE ET DE CONTACT]
Gaetan Michaud Sep. 1993 97 p In FRENCH
(ISBN-0-315-86705-1; CTN-94-61224) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Novel algorithms for studying the contact interference problem in robotics are developed with the objective of introducing them into a new approach for analyzing contact forces during grasping operations. A new approach for analyzing mechanical contacts is utilized for validation. With the aid of Winkler's method and interference algorithms, an analysis of two objects in contact is presented under three different conditions with respect to the types of surfaces which are in contact: a pointed object contacting a plane surface, an edge contacting another edge, and a cylinder contacting a plane surface. The study is based on one of the necessary conditions of the Winkler method, i.e. the analogy to volumetric interference, related to a material interpenetration between two objects. To incorporate the previous elements, a simulator and a data structure are developed. The simulator is used to validate the algorithm of detection of interference between a plane surface and a cylinder. CISTI

DEVELOPMENT OF HIGH-PRESSURE DIAPHRAGMS FOR THE AEDC IMPULSE TUNNEL Final Report, 1 Oct. 1991 - 1 Oct. 1993
J. R. DeWitt Feb. 1994 29 p Prepared in cooperation with Calspan Corp., Arnold AFS, TN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277053; AEDC-TR-93-28) Avail: CASI HC A03

Operation of the AEDC Impulse Tunnel at high stagnation conditions will require diaphragm burst pressures up to approximately 6,900 bars. A hemispherically shaped diaphragm design made of high-strength material has been developed and tested in a test rig for the pressure range from 1,400 to 6,800 bars. Flat diaphragms have been developed and used in the Impulse Tunnel at pressures up to 1,400 bars. A nearly linear relationship between the burst pressure and the ratio of remaining metal thickness to the radius of the cavity into which the diaphragm opens allows linear scaling to different size facilities. MODULAR SIMULATOR SYSTEM (MSS) MANAGEMENT GUIDE Final Report
K. Kelly, J. Brown, G. Kamsickas, and W. Tucker 20 Aug. 1993 48 p
(Contract F33657-86-C-0149)
(AD-A277098; S495-10459-1; ASC-TR-94-5008) Avail: CASI HC A03/MF A01

This document provides guidance and reference information for management personnel in the use of the Modular Simulator System (MSS) design principles. It identifies those unique management considerations required when employing the modular simulator design to a simulation and/or training device. This guide serves as both an educational and decision tool for the manager. The guide will educate the manager in the basic concepts of the modular simulator design and its basis for development. Key program decisions and considerations that must be made when using the modular simulator design are identified and discussed. The advantages and disadvantages of using the modular simulator design along with associated cost/risk analysis, logistics impacts, management implications, lessons learned and basis for invoking the modular simulator design on a procurement/program are provided. (AD-A276966; S495-10441-1; ASC-TR-94-5006) Avail: CASI HC A04

This report provides an executive overview and top level presentation materials for the Modular Simulator System (MSS). It provides a brief overview of the MSS project, system architecture and design, and application alternatives for employing the design to a simulation and/or training device. This report serves as both an educational and decision tool for all levels of management and engineering personnel. This report describes the basic concept of the MSS design and its basis for development. The intent is to support informed decisions regarding the application of the MSS approach to a specific training system development. Additional sources for detailed MSS data are also provided for further reference. DTIC

(Contract F33657-86-C-0149)
(AD-A276967; S495-10440-1; ASC-TR-94-5007) Avail: CASI HC A05/MF A01

This document is intended as an engineering guide for designing a modular simulator. This guide addresses the definition, history, and

characteristics of a modular simulator. Systems and software engineering activities are defined, and modular simulator segment specific and networking design considerations are discussed. This document discusses the modular simulator program design goals and rationale, design rules and guidelines, and lessons learned that have evolved through the program's demonstration phase. The effective use of this guide, in conjunction with the modular simulator architecture documents referenced herein, can substantially reduce the cost, schedule, and risk involved in developing a modular simulator.

AN EVALUATION FRAMEWORK FOR DESIGNING A NIGHT VISION, COMPUTER-BASED TRAINER M.S. Thesis
Eric W. Caudle Dec. 1993 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278005) Avail: CASI HC A04

The mission requirement of low-level, nightime navigation employing night vision goggles has expanded. This has led to a greater demand for training NVG skills and initiated a requirement for a low-cost, desktop, computer-based trainer (CBT). A framework is presented in this thesis that includes a review of the technology available for designing a night vision CBT. System attributes and constraints are identified and analyzed; and evaluation criteria developed to allow for examination of alternative system configurations. Two configurations are developed one PC-based and one workstation-based. These configurations present different cost/benefit components. A sample in graphics capabilities, processor performance and

peripheral support is provided for the two configurations. In addition, cost range estimates are included and possible baseline capabilities established to assist in the determination process. DTIC

CALIBRATION AND VALIDATION STUDIES IN THE LENS FACILITY Final Report, 10 Aug. 1991 - 9 Feb. 1994
Michael Holden 9 Feb. 1994 60 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-91-C-0085)
(AD-A278403; AFOSR-94-0161TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes recent developments in the LENS facility, flow field calibration studies, and aerothermal and aero-optical measurements to evaluate the turbulent flow field characteristics of seeker head configurations in hypervelocity airflow. The development of the LENS facility to run at pressure levels up to 30,000 psi and temperatures up to 14,000 degrees R are reviewed. Issues associated with diaphragm performance, reservoir configuration, throat melting and burning, and modifications to the facility for large recoil loads at high pressure operation are briefly reviewed. Flow field measurements made during calibration studies are compared with computer predictions. Validation studies with simple seeker head aperture configurations in high enthalpy flows are then discussed. The models and aerothermal and aero-optical instrumentation used in these studies are described. The measurements obtained in flows up to 12,000 ft/sec are compared with similar measurements at lower velocities, simple correlation techniques, and detailed computer simulations. DTIC

LDEF MATERIALS RESULTS FOR SPACECRAFT APPLICATIONS
Ann F. Whitaker, comp. and John Gregory, comp. Dec. 1993 533 p Conference held in Huntsville, AL, 27-28 Oct. 1992; sponsored by NASA, Univ. of Alabama, Huntsville, Alabama Space Grant Consortium, and SAMPE
(NASA-CP-3257; M-742; NAS 1.55:3257) Avail: CASI HC A23/MF A04

These proceedings describe the application of LDEF data to spacecraft and payload design, and emphasize where space environmental effects on materials research and development is needed as defined by LDEF data. The LDEF six years of exposure of materials has proven to be by far the most comprehensive source of information ever obtained on the long-term performance of materials in the space environment. The conference provided a forum for materials scientists and engineers to review and critically assess the LDEF results from the standpoint of their relevance, significance, and impact on spacecraft design practice. The impact of the LDEF findings on materials selection and qualification, and the needs and plans for further study, were addressed from several perspectives. Many timely and needed changes and modifications in external spacecraft materials selection have occurred as a result of LDEF investigations. For individual titles, see N94-31013 through N94-31051.

THE PERFORMANCE OF THERMAL CONTROL COATINGS ON LDEF AND IMPLICATIONS TO FUTURE SPACECRAFT **c27**
Donald R. Wilkes (AZ Technology, Huntsville, AL.), Edgar R. Miller (AZ Technology, Huntsville, AL.), Richard J. Mell (AZ Technology, Huntsville, AL.), Paul S. LeMaster (AZ Technology, Huntsville, AL.), and James M. Zwiener *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 3-20 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The stability of thermal control coatings over the lifetime of a satellite or space platform is crucial to the success of the mission. With the increasing size, complexity, and duration of future missions, the stability of these materials becomes even more important. The Long Duration Exposure Facility (LDEF) offered an excellent testbed to study the stability and interaction of thermal control coatings in the low-Earth orbit (LEO) space environment. Several experiments on LDEF exposed thermal control coatings to the space environment. This paper provides an overview of the different materials flown and their stability during the extended LDEF mission. The exposure conditions, exposure environment, and measurements of materials properties (both in-space and postflight) are described. The relevance of the results and the implications to the design and operation of future space vehicles are also discussed. Author (revised)

PERFORMANCE OF SILVERED TEFLON (TRADEMARK) THERMAL CONTROL BLANKETS ON SPACECRAFT **c27**
Gary Pippin, Wayne Stuckey, and Carol Hemminger *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 21-30 (For primary document see N94-31012 09-12)
Avail: CASI HC A02/MF A04

Silverized Teflon (Ag/FEP) is a widely used passive thermal control material for space applications. The material has a very low alpha/e ratio (less than 0.1) for low operating temperatures and is fabricated with various FEP thicknesses (as the Teflon thickness increases, the emittance increases). It is low outgassing and, because of its flexibility, can be applied around complex, curved shapes. Ag/FEP has achieved multiyear lifetimes under a variety of exposure conditions. This has been demonstrated by the Long Duration Exposure Facility (LDEF), Solar Max, Spacecraft Charging at High Altitudes (SCATHA), and other flight experiments. Ag/FEP material has been held in place on spacecraft by a variety of methods: mechanical clamping, direct adhesive bonding of tapes and sheets, and by Velcro(TM) tape adhesively bonded to back surfaces. On LDEF, for example, 5-mil blankets held by Velcro(TM) and clamping were used for thermal control over 3- by 4-ft areas on each of 17 trays. Adhesively bonded 2- and 5-mil sheets were used on other LDEF experiments, both for thermal control and as tape to hold other thermal control blankets in place. Performance data over extended time periods are available from a number of flights. The observed effects on optical properties, mechanical properties, and surface chemistry will be summarized in this paper. This leads to a discussion of performance life estimates and other design lessons for Ag/FEP thermal control material. Author (revised)

SPACE ENVIRONMENT DURABILITY OF BETA CLOTH IN LDEF THERMAL BLANKETS **c27**
Roger C. Linton, Ann F. Whitaker, and Miria M. Finckenor *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 31-45 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Beta cloth performance for use on long-term space vehicles such as Space Station Freedom (S.S. Freedom) requires resistance to the degrading effects of the space environment. The major issues are retention of thermal insulating properties through maintaining optical properties, preserving mechanical integrity, and generating minimal particulates for contamination-sensitive spacecraft surfaces and payloads. The longest in-flight test of beta cloth's durability was on the Long Duration Exposure

Facility (LDEF), where it was exposed to the space environment for 68 months. The LDEF contained 57 experiments which further defined the space environment and its effects on spacecraft materials. It was deployed into low-Earth orbit (LEO) in Apr. 1984 and retrieved Jan. 1990 by the space shuttle. Among the 10,000 plus material constituents and samples onboard were thermal control blankets of multilayer insulation with a beta cloth outer cover and Velcro attachments. These blankets were exposed to hard vacuum, thermal cycling, charged particles, meteoroid/debris impacts, ultraviolet (UV) radiation, and atomic oxygen (AO). Of these space environmental exposure elements, AO appears to have had the greatest effect on the beta cloth. The beta cloth analyzed in this report came from the MSFC Experiment S1005 (Transverse Flat-Plate Heat Pipe) tray oriented approximately 22 deg from the leading edge vector of the LDEF satellite. The location of the tray on LDEF and the placement of the beta cloth thermal blankets are shown. The specific space environment exposure conditions for this material are listed. Author (revised)

SPACE STATION WP-2 APPLICATION OF LDEF MLI RESULTS **c27**
Charles A. Smith, Mark M. Hasegawa, and Cherie A. Jones *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 47-60 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The Cascaded Variable Conductance Heat Pipe Experiment, which was developed by Michael Grote of McDonnell Douglas Electronic Systems Company, was located in Tray F-9 of the Long Duration Exposure Facility (LDEF), where it received atomic oxygen almost normal to its surface. The majority of the tray was covered by aluminized Kapton polyimide multilayer insulation (MLI), which showed substantial changes from atomic oxygen erosion. Most of the outermost Kapton layer of the MLI and the polyester scrim cloth under it were lost, and there was evidence of contaminant deposition which discolored the edges of the MLI blanket. Micrometeoroid and orbital debris (MM/OD) hits caused small rips in the MLI layers, and in some cases left cloudy areas where the vapor plume caused by a hit condensed on the next layer. The MLI was bent gradually through 90 deg at the edges to enclose the experiment, and the Kapton that survived along the curved portion showed the effects of atomic oxygen erosion at oblique angles. In spite of space environment effects over the period of the LDEF mission, the MLI blanket remained functional. The results of the analysis of LDEF MLI were used in developing the standard MLI blanket for Space Station Work Package-2 (WP-2). This blanket is expected to last 30 years when exposed to the low Earth orbit (LEO) environment constituents of atomic oxygen and MM/OD, which are the most damaging to MLI materials. The WP-2 standard blanket consists of an outer cover made from Beta-cloth glass fiber fabric which is aluminized on the interior surface, and an inner cover of 0.076-mm (0.003-in) double-side-aluminized perforated Kapton. The inner reflector layers are 0.0076-mm (0.0003-in) double-side aluminized, perforated Kapton separated by layers of Dacron polyester fabric. The outer cover was selected to be resistant to the LEO environment and durable enough to survive in orbit for 30 years. This paper describes the analyses of the LDEF MLI results, and how these results contributed to the selection of the WP-2 MLI blanket materials and configuration.

ANODIZED ALUMINUM ON LDEF **c26**
Johnny L. Golden *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 61-71 (For primary document see N94-31012 09-12)
(Contracts NAS1-19247; NAS1-18224)
Avail: CASI HC A03/MF A04

A compilation of reported analyses and results obtained for anodized aluminum flown on the Long Duration Exposure Facility (LDEF) was prepared. Chromic acid, sulfuric acid, and dyed sulfuric acid anodized surfaces were exposed to the space environment. The vast majority of the anodized surface on LDEF was chromic acid anodize because of its selection as a thermal control coating for use on the spacecraft primary structure, trays, tray clamps, and space end thermal covers. Reports indicate that the chromic acid anodize was stable in solar absorptance and thermal emittance, but that contamination effects caused increases in absorptance on surfaces exposed to low atomic oxygen fluences. There were some discrepancies, however, in that some chromic acid anodized specimens exhibited significant increases in absorptance. Sulfuric acid anodized surfaces also appeared stable, although very little surface area was available for evaluation. One type of dyed sulfuric acid anodize was assessed as an optical baffle coating and was observed to have improved infrared absorptance characteristics with exposure on LDEF. Author (revised)

FOLLOW-UP ON THE EFFECTS OF THE SPACE ENVIRONMENT ON UHCRE THERMAL BLANKETS **c27**
Francois Levadou and Marc vanEesbeek *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 73-84 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

An overview of the effects of the space environment on the thermal blanket of the UHCRE experiment is presented with an emphasis on atomic oxygen (AO) erosion. A more accurate value for FEP Teflon reaction efficiency is given and corresponds, at normal incidence, to 3.24 10(exp -25) cu cm/atomic, therefore, the FEP Teflon erosion corresponding to the Long Duration Exposure Facility (LDEF) total mission is 29.5 microns. A power 1.44 of the cosine of the incident angle of the oxygen atoms is found. It is shown that this value is not far from the power found using Fergusson's relationship between efficiency and energy of the O-atoms. An hypothesis concerning the effect of oxygen ions (O(+)) is also presented. The presence of oxygen ions may explain the different results obtained from different flights and from laboratory tests. Finally an XPS analysis of Chemglaze Z306(tm) black paint demonstrates the presence of silicone in the paint which may explain part of the contamination found on LDEF.

MODELING OF LDEF CONTAMINATION ENVIRONMENT **c18**
M. Ralph Carruth, Jr., Ray Rantanen, and Tim Gordon *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 87-95 (For primary document see N94-31012 09-12)
Avail: CASI HC A02/MF A04

The Long Duration Exposure Facility (LDEF) satellite was unique in many ways. It was a large structure that was in space for an extended period of time and was stable in orientation relative to the velocity vector. There are obvious and well documented effects of contamination and space environment effects on the LDEF satellite. In order to examine the interaction of LDEF with its environment and the resulting effect on the satellite, the Integrated Spacecraft Environments Model (ISEM) was used to model the LDEF-induced neutral environment at several different times and altitudes during the mission. SPACECRAFT CONTAMINATION ISSUES FROM LDEF: ISSUES FOR DESIGN **c18**
Gary Pippin and Russ Crutcher *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 97-103 (For primary document see N94-31012 09-12)
(Contracts NAS1-19247; NAS1-18224)
Avail: CASI HC A02/MF A04

Many contamination sources have been identified on the Long Duraticn Exposure Facility (LDEF). Effects of contamination from these sources are being quantified and have been reported on in several papers. For a designer, the essential question is how much contamination from all sources can be tolerated without causing a given spacecraft system to degrade below a critical performance level, or fail altogether. Even a rudimentary knowledge of the mechanisms by which molecular and particulate contamination can occur will allow simple design options to be chosen to circumvent potential contamination problems and reduce contamination levels. Because of the varied nature and condition of hardware used on LDEF experiments, examples of many types of contamination were seen and these provide a useful guide to expected performance of many types of materials in space environments. MODEL OF SPACECRAFT ATOMIC OXYGEN AND SOLAR EXPOSURE MICROENVIRONMENTS **c90**
R. J. Bourassa and H. G. Pippin *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 105-114 (For primary document see N94-31012 09-12)
(Contract NAS1-19247)
Avail: CASI HC A02/MF A04

Computer models of environmental conditions in Earth orbit are needed for the following reasons: (1) derivation of material performance parameters from orbital test data, (2) evaluation of spacecraft hardware designs, (3) prediction of material service life, and (4) scheduling spacecraft maintenance. To meet these needs, Boeing has developed programs for modeling atomic oxygen (AO) and solar radiation exposures. The model allows determination of AO and solar ultraviolet (UV) radiation exposures for spacecraft surfaces (1) in arbitrary orientations with respect to the direction of spacecraft motion, (2) overall ranges of solar conditions, and (3) for any mission duration. The models have been successfully applied to prediction of experiment environments on the Long Duration Exposure Facility (LDEF) and for analysis of selected hardware designs for deployment on other spacecraft. The work on these models has been reported at previous LDEF conferences. Since publication of these reports, a revision has been made to the AO calculation for LDEF, and further work has been done on the microenvironments model for solar exposure. Author

The Long Duration Exposure Facility (LDEF) satellite carried 57 experiments that were designed to define the low-Earth orbit (LEO) space environment and to evaluate the impact of this environment on potential engineering materials and material processes. Deployed by the Shuttle Challenger in April of 1984, LDEF made over 32,000 orbits before being retrieved nearly 6 years later by the Shuttle Columbia in January of 1990. The Solar Array Passive LDEF Experiment (SAMPLE) AO171 contained approximately 300 specimens, representing numerous material classes and material processes. AO171 was located on LDEF in position A8 at a yaw of 38.1 degrees from the ram direction and was subjected to an atomic oxygen (AO) fluence of 6.93 x 10(exp 21) atoms/sq cm. LDEF AO171 data, as well as short-term shuttle data, will be discussed in this paper as it applies to engineering design applications of composites, bulk and thin film polymers, glassy ceramics, thermal control paints, and metals subjected to AO erosion. PERFORMANCE OF SELECTED POLYMERIC MATERIALS ON LDEF **c27**
Philip R. Young, Wayne s. Slemp, and Bland A. Stein *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 125-142 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The NASA Long Duration Exposure Facility (LDEF) provided a unique environmental exposure of a wide variety of materials for potential advanced spacecraft application. This paper examines the molecular level response of selected polymeric materials which flew onboard this vehicle. Polymers include epolyimide, polysulfone, and polystyrene film and polyimide, polysulfone, and epoxy matrix resin/graphite fiber reinforced composites. Several promising experimental films were also studied. Most specimens received 5.8 years of low Earth orbital (LEO) exposure on LDEF. Several samples received on 10 months of exposure. Chemical characterization techniques included ultraviolet-visible and infrared spectroscopy, thermal analysis, x-ray photoelectron spectroscopy, and selected solution property measurements. Results suggest that many molecular level effects present during the first 10 months of exposure were not present after 5.8 years of exposure for specimens on or near Row 9. Increased AO fluence near the end of the mission likely eroded away much environmentally induced surface phenomena. The objective of this work is to provide fundamental information for use in improving the performance of polymeric materials for LEO application. A secondary objective is to gain an appreciation for the constraints and limitations of results from LDEF polymeric materials experiments. Author

ATOMIC OXYGEN INTERACTION AT DEFECT SIGHTS IN PROTECTIVE COATINGS ON POLYMERS FLOWN ON LDEF **c27**
Bruce A. Banks, Kim K. deGroh, Bruce M. Auer, Linda Gebauer, and Cynthia LaMoreaux *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 143-158 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Although the Long Duration Exposure Facility (LDEF) has exposed materials with a fixed orientation relative to the ambient low-Earth-orbital environment, arrival of atomic oxygen is angularly distributed as a result of the atomic oxygen's high temperature Maxwellian velocity distribution and the LDEF's orbital inclination. Thus, atomic oxygen entering defects in protective coatings on polymeric surfaces can cause wider undercut cavities than the size of the defect in the protective coating. Because only a small fraction of atomic oxygen reacts upon first impact with most polymeric materials, secondary reactions with lower energy thermally accommodated atomic oxygen can occur. The secondary reactions of scattered and/or thermally accommodated atomic oxygen also contribute to widening the undercut cavity beneath the protective coating defect. As the undercut cavity enlarges, exposing more polymer, the probability of atomic oxygen reacting with underlying polymeric material increases because of multiple opportunities for reaction. Thus, the effective atomic oxygen erosion yield for atoms entering defects increases above that of the unprotected material. Based on the results of analytical modeling and computational modeling, aluminized Kapton multilayer insulation exposed to atomic oxygen on row 9 lost the entire externally exposed layer of polyimide Kapton, yet based on the results of this investigation, the bottom surface aluminum film must have remained in place, but crazed. Atomic oxygen undercutting at defect sites in protective coatings on graphite epoxy composites indicates that between 40 to 100 percent of the atomic oxygen thermally accommodates upon impact, and that the reaction probability of thermally accommodated atomic oxygen may range from 7.7 x 10(exp -6) to 2.1 x 10(exp -3), depending upon the degree of thermal accommodation upon each impact. FLUORESCENCE OBSERVATIONS OF LDEF EXPOSED MATERIALS AS AN INDICATOR OF INDUCED MATERIAL REACTIONS **c25**
Roger C. Linton, Ann F. Whitaker, and Rachel R. Kamenetzky *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 159-178 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Observations and measurements of induced changes in the fluorescent emission of materials exposed to the space environment on the Long Duration Exposure Facility (LDEF) have revealed systematic patterns of material-dependent behavior. These results have been supplemented by inspection of similar materials exposed on previous Space Shuttle Missions and in laboratory testing. The space environmental factors affecting the fluorescence of exposed materials have been found to include (but are not necessarily limited to) solar ultraviolet (UV) radiation, atomic oxygen (AO), thermal vacuum exposure, and synergistic combinations of these factors. Observed changes in material fluorescent behavior include stimulation, quenching, and spectral band shifts of emission. For example, the intrinsic yellow fluorescence of zinc oxide pigmented thermal control coatings undergoes quenching as a result of exposure, while coloration is stimulated in the fluorescent emission of several polyurethane coating materials. The changes in fluorescent behavior of these materials are shown to be a revealing indicator of induced material reactions as a result of space environmental exposure. Author

LASER-INDUCED FLUORESCENCE OF SPACE-EXPOSED POLYURETHANE **c27**

Ralph H. Hill, Jr. *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 179-192 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The object of this work was to utilize laser-induced fluorescence technique to characterize several samples of space-exposed polyurethane. These samples were flown on the Long Duration Exposure Facility (LDEF), which was in a shuttle-like orbit for nearly 6 years. Because of our present work to develop laser-induced-fluorescence inspection techniques for polymers, space-exposed samples and controls were lent to us for evaluation. These samples had been attached to the outer surface of LDEF; therefore, they were subjected to thermal cycling, solar ultraviolet radiation, vacuum, and atomic oxygen. It is well documented that atomic oxygen and ultraviolet exposure have detrimental effects on many polymers. This was a unique opportunity to make measurements on material that had been naturally degraded by an unusual environment. During our past work, data have come from artificially degraded samples and generally have demonstrated a correlation between laser-induced fluorescence and tensile strength or elasticity. Author

ON THE LINEARITY OF FAST ATOMIC OXYGEN EFFECTS **c18**
J. C. Gregory *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 193-198 (For primary document see N94-31012 09-12)
Avail: CASI HC A02/MF A04

The effect of bombardment of 8 km per second atomic oxygen (AO) experienced by exposed surfaces of satellites in low Earth orbit must be considered in the selection of materials to be used in instruments and functional systems on these satellites. The degree of importance of the effects varies widely depending on the material, the application, and the exposure (fluence of atoms) to which it is to be subjected. Some highly erodible thin polymer film materials might be considered unacceptable on a long-lived space station, but may be perfectly serviceable on a normal shuttle flight. In order to determine the acceptability of a material for a particular environment, a designer must know the relationship between the magnitude of the effect (for example, mass-loss) and the magnitude of the fluence. To determine this relationship, we need data over a useful range of fluence. Until the return of the Long Duration Exposure Facility (LDEF), the bulk of the data on materials effects was obtained from a few shuttle flights, and the bulk of that data from the flight of experiment Evaluation of Oxygen Interaction with Materials (EOIM-2) on STS-8 in 1983. EOIM-2 obtained a fluence of 3.5 x 10(exp 20) atoms cm(exp -2), while the LDEF fluence approached 10(exp 22) atoms cm(exp -2), or about 30 times greater. Although other flight exposures had been obtained with lower fluences, considerable uncertainty was attached to these results because of the possibility of large relative systematic errors and of other factors such as sweeping angle of attack. In the future, it is hoped that simulation facilities in the laboratory will allow testing of materials without the necessity of flying them in space. In addition, if the relationship of effect with oxygen fluence is well determined, it should not be necessary to expose a material for an entire mission fluence. In this paper, we shall avoid a comparison of flight data with results from simulators, though that comparison is important for the materials community. The present discussion is limited to flight data only. Author

IMPACT OF LDEF PHOTOVOLTAIC EXPERIMENT FINDINGS UPON SPACECRAFT SOLAR ARRAY DESIGN AND DEVELOPMENT REQUIREMENTS **c44**
Leighton E. Young *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 201-215 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Photovoltaic cells (solar cells) and other solar array materials were flown in a variety of locations on the Long Duration Exposure Facility (LDEF). With respect to the predicted leading edge, solar array experiments were located at 0 degrees (row 9), 30 degrees (row 8) and 180 degrees (row 3). Postflight estimates of location of the experiments with respect to the velocity vector add 8.1 degrees to these values. Experiments were also located on the Earth end of the LDEF longitudinal axis. Types and magnitudes of detrimental effects differ between the locations with some commonality. Postflight evaluation of the solar array experiments reveal that some components/materials are very resistant to the environment to which they were exposed while others need protection, modification, or replacement. Interaction of materials with atomic oxygen (AO), as an area of major importance, was dramatically demonstrated by LDEF results. Information gained from the LDEF flight allows array developers to set new requirements for on-going and future technology and flight component development. Author

This report concerns two types of optical components: multilayer filters and mirrors, and self-scanned imaging arrays using charge coupled device (CCD) readouts. For the filters and mirrors, contamination produces a strong reduction in transmittance in the ultraviolet spectral region, but has little or no effect in the visible and infrared spectral regions. Soft substrates containing halides are unsatisfactory as windows or substrates. Materials choice for dielectric layers should also reflect such considerations. Best performance is also found for the harder materials. Compaction of the layers and interlayer diffusion causes a blue shift in center wavelength and loss of throughput. For sensors using CCD's, shifts in gate voltage and reductions in transfer efficiency occur. Such effects in CCD's are in accord with expectations of the effects of the radiation dose on the device. Except for optical fiber, degradation of CCD's represents the only ionizing-radiation induced effect on the Long Duration Exposure Facility (LDEF) optical systems components that has been observed. PHYSICAL PROPERTIES OF GLASSES EXPOSED TO EARTH-FACING AND TRAILING-SIDE ENVIRONMENTS ON LDEF **c27**
David E. Wiedlocher, Donald L. Kinser, Robert A. Weller, Robert A. Weeks, and Marcus H. Mendenhall *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 227-243 (For primary document see N94-31012 09-12)
(Contracts NAG8-156; NAS8-32695; L-17761D)
Avail: CASI HC A03/MF A04

The exposure of 108 glass samples and 12 glass-ceramic samples to Earth-orbit environments permitted measurements which establish the effects of each environment. Examination of five glass types and one glass ceramic located on both the Earth-facing side and the trailing edge revealed no reduction in strength within experimental limits. Strength measurements subjected less than 5 percent of the sample surface area to stresses above 90 percent of the glass's failure strength. Seven micrometeorite or space debris impacts occurred on trailing edge samples. One of those impacts occurred in a location which was subjected to 50 percent of the applied stress at failure. Micrometeorite or space debris impacts were not observed on Earth-facing samples. The physical shape and structure of the impact sites were carefully examined using stereographic scanning electron microscopy. These impacts induce a stress concentration at the damaged region which influences mechanical strength. The flaw size produced by such damage was examined to determine the magnitude of strength degradation in micrometeorite or space-debris impacted glasses. Scanning electron microscopy revealed topographical details of impact sites which included central melt zones and glass fiber production. The overall crater structure is similar to much larger impacts of large meteorite on the Moon in that the melt crater is surrounded by shocked regions of material which fracture zones and spall areas. Residual stresses arising from shock compression and cooling of the fused zone cannot currently be included in fracture mechanics analyses based on simple flaw size examination. Author

MORPHOLOGY CORRELATION OF CRATERS FORMED BY HYPERVELOCITY IMPACTS **c39**
Gary D. Crawford, M. Frank Rose, and Ralph H. Zee *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications

Dec. 1993 p 245-257 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Dust-sized olivine particles were fired at a copper plate using the Space Power Institute hypervelocity facility, simulating micrometeoroid damage from natural debris to spacecraft in low-Earth orbit (LEO). Techniques were developed for measuring crater volume, particle volume, and particle velocity, with the particle velocities ranging from 5.6 to 8.7 km/s. A roughly linear correlation was found between crater volume and particle energy which suggested that micrometeoroids follow standard hypervelocity relationships. The residual debris analysis showed that for olivine impacts of up to 8.7 km/s, particle residue is found in the crater. By using the Space Power Institute hypervelocity facility, micrometeoroid damage to satellites can be accurately modeled. Author

MICROMETEOROID/SPACE DEBRIS EFFECTS ON MATERIALS c39
James M. Zwiener and Miria M. Finckenor *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 259-279 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The Long Duration Exposure Facility (LDEF) micrometeoroid/space debris impact data has been reduced in terms that are convenient for evaluating the overall quantitative effect on material properties. Impact crater flux has been evaluated as a function of angle from velocity vector and as a function of crater size. This data is combined with spall data from flight and ground testing to calculate effective solar absorption and emittance values versus time. Results indicate that the surface damage from micrometeoroid/space debris does not significantly affect the overall surface optical thermal physical properties. Of course the local damage around impact craters radically alter optical properties. Damage to composites and solar cells on an overall basis was minimal. Author

THERMAL-VACUUM RESPONSE OF POLYMER MATRIX COMPOSITES IN SPACE c24
R. C. Tennyson and R. Matthews *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 283-299 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

This report describes a thermal-vacuum outgassing model and test protocol for predicting outgassing times and dimensional changes for polymer matrix composites. Experimental results derived from 'control' samples are used to provide the basis for analytical predictions to compare with the outgassing response of Long Duration Exposure Facility (LDEF) flight samples. Coefficient of thermal expansion (CTE) data are also presented. In addition, an example is given illustrating the dimensional change of a 'zero' CTE laminate due to moisture outgassing. Author

Over 200 graphite/aluminum and graphite/magnesium composites were flown on the leading and trailing edges of LDEF on the Advanced Composites Experiment. The performance of these composites was evaluated by performing scanning electron microscopy and x-ray photoelectron spectroscopy of exposed surfaces, optical microscopy of cross sections, and on-orbit and postflight thermal expansion measurements. Graphite/aluminum and graphite/magnesium were found to be superior to graphite/polymer matrix composites in that they are inherently resistant to atomic oxygen and are less susceptible to thermal cycling induced microcracking. The surface foils on graphite/aluminum and graphite/magnesium protect the graphite fibers from atomic oxygen and from impact damage from small micrometeoroid or space debris particles. However, the surface foils were found to be susceptible to thermal fatigue cracking arising from contamination embrittlement, surface oxidation, or stress risers. Thus, the experiment reinforced requirements for carefully protecting these composites from prelaunch oxidation or corrosion, avoiding spacecraft contamination, and designing composite structures to minimize stress concentrations. On-orbit strain measurements demonstrated the importance of through-thickness thermal conductivity in composites to minimize thermal distortions arising from thermal gradients. Because of the high thermal conductivity of aluminum, thermal distortions were greatly reduced in the LDEF thermal environment for graphite/aluminum as compared to graphite/magnesium and graphite/polymer composites. The thermal expansion behavior of graphite/aluminum and graphite/magnesium was stabilized by on-orbit thermal cycling in the same manner as observed in laboratory tests. Author

SPACE ENVIRONMENTAL EFFECTS ON POLYMER COMPOSITES: RESEARCH NEEDS AND OPPORTUNITIES c24
Bor Z. Jang, J. Bianchi, Y. M. Liu, and C. P. Chang *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 319-333 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The long-term performance of polymer-based composites in the space environment is discussed. Both thermoset and thermoplastic matrix composites are included in this discussion. Previous efforts on the space environmental effects on composites are briefly reviewed. Focus of this review is placed on the effects of hygrothermal stresses, atomic oxygen, ultraviolet (UV), and space debris/micrometeoroid impacts along with the potential synergism. Potential approaches to estimating the residual strength of polymer composites after exposure to atomic oxygen erosion or space debris/micrometeoroid impact are evaluated. New ground-based data are then utilized to illustrate the effects of atomic oxygen and thermal cycling on the failure behavior of polymer composites. Finally, research needs, challenges, and opportunities in the field of space environmental effects on composite materials are highlighted. Author

LOW-EARTH ORBIT EFFECTS ON ORGANIC COMPOSITE MATERIALS FLOWN ON LDEF c24
Pete E. George and Harry W. Dursch *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 335-354 (For primary document see N94-31012 09-12)
(Contracts NAS1-18224; NAS1-19247)
Avail: CASI HC A03/MF A04

Over 35 different types of organic matrix composites were flown as part of 11 different experiments onboard the NASA Long Duration Exposure Facility (LDEF) satellite. This materials and systems experiment satellite flew in low-earth orbit (LEO) for 69 months. For that period, the experiments were subjected to the LEO environment including atomic oxygen (AO), ultraviolet (UV) radiation, thermal cycling, microvacuum, meteoroid and space debris (M&D), and particle radiation. Since retrieval of the satellite in January of 1990, the principal experiment investigators have been deintegrating, examining, and testing the materials specimens flown. The most detrimental environmental effect on all organic matrix composites was material loss due to AO erosion. AO erosion of uncoated organic matrix composites (OMC) facing the satellite ram direction was responsible for significant mechanical property degradations. Also, thermal cycling-induced microcracking was observed in some nonunidirectional reinforced OMC's. Thermal cycling and outgassing caused significant but predictable dimensional changes as measured in situ on one experiment. Some metal and metal oxide-based coatings were found to be very effective at preventing AO erosion of OMC's. However, M&D impacts and coating fractures which compromised these coatings allowed AO erosion of the underlying OMC substrates. The findings for organic matrix composites flown on the LDEF are summarized and the LEO environmental factors, their effects, and the influence on space hardware design factors for LEO applications are identified. A wide variety of materials and experiment support hardware were flown on the Long Duration Exposure Facility (LDEF). Postflight testing has determined the effects of the almost 6 years of low-earth orbit (LEO) exposure on this hardware. An overview of the results are presented. Hardware discussed includes adhesives, fasteners, lubricants, data storage systems, solar cells, seals, and the LDEF structure. Lessons learned from the testing and analysis of LDEF hardware is also presented.

Avail: CASI HC A02/MF A04

The Long Duration Exposure Facility (LDEF) was composed of and contained a wide array of materials, representing the largest collection of materials flown for space exposure and returned for ground-based analyses to date. The results and implications of the data from these materials are the foundation on which future space missions will be built. The LDEF Materials Special Investigation Group (MSIG) has been tasked with establishing and developing data bases to document these materials and their performance to assure not only that the data are archived for future generations but also that the data are available to the space user community in an easily accessed, user-friendly form. The format and content of the data bases developed or being developed to accomplish this task are discussed. The hardware and software requirements for each of the three data bases are discussed along with current availability of the data bases.

GROUND-BASED SIMULATION OF LEO ENVIRONMENT: INVESTIGATIONS OF A SELECT LDEF MATERIAL: FEP TEFLON (TRADEMARK) **c27**
Jon B. Cross (Los Alamos National Lab., NM.) and Steven L. Koontz *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 379-389 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The Long Duration Exposure Facility (LDEF) has produced a wealth of data on materials degradation in the low earth orbit (LEO) space environment and has conclusively shown that surface chemistry (as opposed to surface physics-sputtering) is the key to understanding and predicting the degradation of materials in the LEO environment. It is also clear that materials degradation and spacecraft contamination are closely linked and that the fundamental mechanisms responsible for this linking are in general not well understood especially in the area of synergistic effects. The study of the fundamental mechanisms underlying materials degradation in LEO is hampered by the fact that the degradation process itself is not observed during the actual exposure to the environment. Rather the aftermath of the degradation process is studied, i.e., the material that remains after exposure is observed and mechanisms are proposed to explain the observed results. The EOIM-3 flight experiment is an attempt to bring sophisticated diagnostic equipment into the space environment and monitor the degradation process in real time through the use of mass spectrometry. More experiments of this nature which would include surface sensitive diagnostics (Auger and photoelectron spectroscopes) are needed to truly unravel the basic chemical mechanisms involved in the materials degradation process. Since these in-space capabilities will most likely not be available in the near future, ground-based LEO simulation facilities employing sophisticated diagnostics are needed to further advance the basic understanding of the materials degradation mechanisms. The LEO simulation facility developed at Los Alamos National Laboratory has been used to investigate the atomic oxygen/vacuum ultraviolet (AO/VUV) enhanced degradation of FEP Teflon. The results show that photo-ejection of polymer fragments occur at elevated temperature (200 C), that VUV synergistic rare gas sputtering of polymer fragments occur even at 25 C, and that combined OA/VUV interaction produces a wide variety of gas phase reaction products. AN OVERVIEW OF THE EVALUATION OF OXYGEN INTERACTION WITH MATERIALS-THIRD PHASE (EOIM-3) EXPERIMENT: SPACE SHUTTLE MISSION 46 **c25**
Lubert J. Leger, Steven L. Koontz, James T. Visentine, and Donald Hunton *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 391-417 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

The interaction of the atomic oxygen (AO) component of the low earth orbit (LEO) environment with spacecraft materials has been the subject of several flight experiments over the past 11 years. The effect of AO interactions with materials has been shown to be significant for long-lived spacecraft such as Space Station Freedom and has resulted in materials changes for externally exposed surfaces. The data obtained from previous flight experiments, augmented by limited ground-based evaluation, have been used to evaluate hardware performance and select materials. Questions pertaining to the accuracy of this data base remain, resulting from the use of long-term ambient density models to estimate the O-atom fluxes and fluences needed to calculate materials reactivity in short-term flight experiments. The EOIM-3 flight experiment was designed to produce benchmark AO reactivity data and was carried out during STS-46. Ambient density measurements were made with a quadrupole mass spectrometer which was calibrated for AO measurements in a unique ground-based test facility. The combination of these data with the predictions of ambient density models allows an assessment of the accuracy of measured reaction rates on a wide variety of materials, many of which had never been tested in LEO before. The mass spectrometer is also used to obtain a better definition of the local neutral and plasma environments resulting from interaction of the ambient atmosphere with various spacecraft surfaces. In addition, the EOIM-3 experiment was designed to produce information on the effects of temperature, mechanical stress, and solar exposure on the AO reactivity of a wide range of materials. An overview of the EOIM-3 methods and results are presented. Author (revised)

ANALYSIS OF LEADING EDGE AND TRAILING EDGE COVER GLASS SAMPLES BEFORE AND AFTER TREATMENT WITH ADVANCED SATELLITE CONTAMINATION REMOVAL TECHNIQUES **c27**
S. P. Hotaling *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 419-436 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Two samples from Long Duration Exposure Facility (LDEF) experiment M0003-4 were analyzed for molecular and particulate contamination prior to and following treatment with advanced satellite contamination removal techniques (CO2 gas/solid jet spray and oxygen ion beam). The pre- and post-cleaning measurements and analyses are presented. The jet spray removed particulates in seconds. The low energy reactive oxygen ion beam removed 5,000 A of photo polymerized organic hydrocarbon contamination in less than 1 hour. Spectroscopic analytical techniques were applied to the analysis of cleaning efficiency including: Fourier transform infrared, Auger, x ray photoemissions, energy dispersive x ray, and ultraviolet/visible. The results of this work suggest that the contamination studied here was due to spacecraft self-contamination enhanced by atomic oxygen plasma dynamics and solar UV radiation. These results also suggest the efficacy for the jet spray and ion beam contamination control technologies for spacecraft optical surfaces. Author (revised)

PRELIMINARY RESULTS FROM THE CONCAP-2-01 AND EIOM-3 EXPERIMENTS ON STS-46 **c27**
John C. Gregory and Ganesh N. Raikar *In* NASA. Marshall Space Flight

Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 439-453 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

CONCAP-2-01 (complex autonomous payload, first flight) was the maiden flight of 'CONCAP-2,' a secondary payload, utilizing the get-away special (GAS) carrier system, sponsored by the Consortium for Materials Development in Space (CMDS) at the University of Alabama in Huntsville (UAH). A host of materials such as high-T(sub c) superconductor samples, metal films, polymers, carbons, and semiconducting materials were exposed to a low earth orbit (LEO) environment. We have also measured on orbit the changes in the electrical resistance of some of the high-T(sub c) materials plus carbon and silver dosimeters exposed to the space environment. The preliminary results of this experiment are compared with those from EOIM-3, both of which flew on STS-46. Author (revised)

EFFECTS OF ORBITAL EXPOSURE ON RTV DURING THE LDEF MISSION **c25**

William E. Brower, Jr., S. V. Golub, and Robert A. Bauer *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 455-463 (For primary document see N94-31012 09-12)
Avail: CASI HC A02/MF A04

Thermomechanical analysis (TMA), differential scanning calorimetry (DSC), and thermogravimetric analysis (TGA) were performed on samples of RTV 511 exposed on the Long Duration Exposure Facility (LDEF) mission for 6 years in orbit and unexposed RTV 511 control samples. Slices 20- to 400-microns thick were removed from the exposed surface down to a depth of 1,500 microns through the 3-mm thick samples. The TMA and DSC results, which arise from the entire slice and not just its surface, showed no significant differences between the LDEF exposed and the control samples. TMA scans were run from ambient to 500 C; results were compared by a tabulation of the onset temperatures for flow. DSC scans were run from ambient to 600 C; no endotherms or exotherms occurred over the range observed. What appear to be glass transition temperatures were compared for the samples as a function of section depth within the sample and between the exposed and control samples. The TGA scans from 25 to 900 C, which arise from the surface of the sample initially, showed a slight increase in the top most 105-micron slice (the exposed, discolored side) in the weight loss at 600 C in oxygen. This weight loss dropped to bulk values at the next slice below the top section, a mean depth of 258 microns. The control sample also showed an increase in weight loss as the top surface was approached, but the 600 C weight losses were very inconsistent. The LDEF RTV sample appears to be mechanically undamaged, with a surface layer which oxidizes slightly faster as a result of orbital exposure. Author

SPACECRAFT MATERIALS: COMPARISON BETWEEN FLIGHT RESULTS OBTAINED ON LDEF AND MIR **c18**

Jean-Claude Guillaumon and Alain Paillous *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 485-498 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Two flight experiments dedicated to the study of the performance of materials in space have been carried out. Material samples have been exposed passively to low-Earth orbit (LEO) environment, then retrieved for laboratory study. The first experiment was conducted in the framework of the FRECOPA project and was flown on the trailing edge of the Long Duration Exposure Facility (LDEF) (exposure to vacuum and ultraviolet (UV) radiation for 5.5 years). The experiment COMES was installed outside of the MIR space station during an extravehicular activity; it was exposed to vacuum, O-atoms, and UV radiation for 1.1 year; and it was brought back to Earth by cosmonauts. The difference in exposure conditions and the use of transparent filters protecting some samples of COMES enable to differentiate the effects of UV radiation and oxygen atoms. The degradations of several thermal control coatings (paints, metalized polymeric films with and without ITO), structural materials, and optical components have been observed, measured, and compared after these two flight experiments. This paper summarizes various 'lessons learned' that can be used to identify aspects of space aging, to orient future research in this field, and to assist in spacecraft design. Author

CHARACTERIZATION OF POLYMER DECOMPOSITION PRODUCTS BY LASER DESORPTION MASS SPECTROMETRY **c27**

Joan B. Pallix, Kenneth A. Lincoln, Charles J. Miglionico, Robert E. Roybal, Charles Stein, and Jon H. Shively *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 499-509 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

Laser desorption mass spectrometry has been used to characterize the ash-like substances formed on the surfaces of polymer matrix composites (PMC's) during exposure on LDEF. In an effort to minimize fragmentation, material was removed from the sample surfaces by laser desorption and desorbed neutrals were ionized by electron impact. Ions were detected in a time-of-flight mass analyzer which allows the entire mass spectrum to be collected for each laser shot. The method is ideal for these studies because only a small amount of ash is available for analysis. Three sets of samples were studied including C/polysulfone, C/polyimide and C/phenolic. Each set contains leading and trailing edge LDEF samples and their respective controls. In each case, the mass spectrum of the ash shows a number of high mass peaks which can be assigned to fragments of the associated polymer. These high mass peaks are not observed in the spectra of the control samples. In general, the results indicate that the ash is formed from decomposition of the polymer matrix. Author

DESIGN APPLICATION AND DEVELOPMENT OF SPACECRAFT IN LEO UTILIZING LDEF RESULTS **c18**

George B. Rauch, Jr. and Richard D. Sudduth *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 511-523 (For primary document see N94-31012 09-12)
Avail: CASI HC A03/MF A04

In general, the results from the Long Duration Exposure Facility (LDEF) have provided much useful information on material sensitivity in the low-Earth orbit (LEO) environment. This is particularly true for selected materials such as thermal control coatings, composites, polymers, fasteners and solar cells. However, LDEF material sensitivity data for other materials like glasses, glass coatings, lubricants, adhesives and seal materials were limited. Some of this important LDEF material sensitivity data has not yet been addressed in detail at the LDEF meetings. The type of material information needed in the design and development of a new spacecraft in LEO depends to a large extent on program phase. In early program phases it is only necessary to have material sensitivity data to determine what materials may or may not work. Later program phases require details on the material strength, optical properties, and/or other long term survivability requirements for materials in LEO. Unfortunately, documentation of exposure results for many materials sensitivity experiments that flew on LDEF has not yet been summarized in a convenient form for use by multiple users. Documentation of this data in a form convenient for scientists, engineers as well as technicians remains a significant area of concern for the aerospace industry. Many of the material experiments that flew on LDEF were only designed to measure material sensitivity for one year in an LEO environment. However, some materials expected to survive one year simply did not survive the 5.8 years that LDEF eventually remained in orbit. Therefore

the survivability of several materials in an LEO environment was determined by default. Most of the LDEF materials experiments were not designed to establish long term material survivability data. This long term material survivability data is particularly useful in later program phases of spacecraft development. The lack of more controlled materials experiments to determine long term material survivability was one of the major limitations of many LDEF experiments. The identified need for this critical information on the long term survivability offers a challenge to possible future LDEF type experiments. Author

MSFC ORBITAL SPACECRAFT DEVELOPMENT EMPHASES FOR THIS DECADE **c18**

Robert J. Schwinghamer *In its* LDEF Materials Results for Spacecraft Applications Dec. 1993 p 525-531 (For primary document see N94-31012 09-12)

Avail: CASI HC A02/MF A04

Historically, the Marshall Space Flight Center (MSFC) has been responsible for significant accomplishments in the area of developing both manned and unmanned spacecraft. MSFC is presently involved in many of NASA's largest and most prominent programs, with some operational, others being readied for flight, and still others in various stages of design and development. Examples of MSFC programs being designed or developed are Space Station Freedom (S.S. Freedom), the Advanced X-Ray Astrophysics Facility (AXAF) which includes imaging and spectroscopy facilities, the Laser Atmospheric Wind Sounder (LAWS), and the Lunar Ultraviolet Telescope Experiment (LUTE), with Spacelab and Tethered Satellite System (TSS) as examples of current operational MSFC spacecraft. The information obtained from the Long Duration Exposure Facility (LDEF) will aid the design process and life predictions for these and all future spacecraft. A second LDEF is presently being considered. All of these projects will be briefly described in this paper. Author

AN OVERVIEW OF THE ON-ORBIT CONTAMINATION OF THE LONG DURATION EXPOSURE FACILITY (LDEF) **c18**

W. K. Stuckey *In* NASA. Marshall Space Flight Center, LDEF Materials Results for Spacecraft Applications Dec. 1993 p 533-539 (For primary document see N94-31012 09-12)

Avail: CASI HC A02/MF A04

Contamination that leads to degradation of critical surfaces becomes a vital design issue for many spacecraft programs. One of the processes that must be considered is the on-orbit accumulation of contaminants. The Long Duration Exposure Facility (LDEF) has presented an opportunity to examine the deposits on surfaces returned from orbit in order to help in understanding the deposition processes and the current models used to predict spacecraft contamination levels. The results from various investigators on the contamination of LDEF have implications for material selection, contamination models, and contamination control plans for the design of future spacecraft. The Long Duration Exposure Facility (LDEF) served as the ultimate laboratory to provide combined space environmental effects on materials. The LDEF structure and its 57 experiments contained an estimated 12,000 to 14,000 specimens of materials and materials processes. It not only provided information about the resistance of these materials to the space environment but gives us direction into future needs for spacecraft materials development and testing. This paper provides an overview of the materials effects observed on the satellite and suggests recommendations for the future work in space-qualified materials development and space environmental simulation. The main development approaches and some technologies developed in support of the different objectives of the Dutch Utilization Center (DUC) are reported. The DUC acts as a point of coordination of Dutch user support activities. The support needs of the user are analyzed and from there the required support efforts of the entities in the Dutch User Support Organization (DUSO) are activated. The main objectives of the DUSO are to promote the availability of the Columbus Space Station infrastructure among potential Dutch users, and to assist the users during the process of experiment definition, development, execution, and results evaluation. The DUSO support activities cover promotion and familiarization, and administrative, scientific, technical, and operational support to microgravity and space experimentation. The DUC developmental approaches consist of two approaches: a top down or formal approach; and a bottom up approach. ESA

THE SECOND ANNUAL INTERNATIONAL SPACE UNIVERSITY ALUMNI CONFERENCE

Les Johnson, comp. and Paul A. Robinson, comp. Washington Feb. 1994 151 p Conference held in Huntsville, AL, 6 Aug. 1993; sponsored by International Space Univ., Inc.

(NASA-CP-3253; M-738; NAS 1.55:3253) Avail: CASI HC A08/MF A02

The papers presented at the conference reflect the multidisciplinary nature of the International Space University (ISU) and its alumni. The first papers presented hold special relevance to the design projects, and cover such topics as lunar-based astronomical instrumentation, solar lunar power generation, habitation on the moon, and the legal issues governing multinational astronauts conducting research in space. The next set of papers cover various technical issues such as project success assessment, satellite networks and space station dynamics, thus reflecting the diverse backgrounds of the ISU alumni. For individual titles, see N94-31426 through N94-31438.

The galactic cosmic-ray flux incident on the Moon was examined for its potential adverse impact on the performance of the large lunar telescope (LLT) proposed as a part of NASA's Space Exploration Initiative (SEI). Noise produced by the cosmic-ray flux in the charge coupled devices (CCD's) to be used as the primary photodetector in the telescope was estimated. It was calculated that approximately 2.5 m of regolith would provide the shielding necessary to reduce the noise to an acceptable level. Dust is an omnipresent environmental concern for any human-assisted or robotic scientific instruments deployed on the Moon. The degree to

which dust poses an operational risk to the telescope was examined. Three potential methods for reducing this risk were identified: locating scientific instruments at remote locations; utilizing a prepared, dust-free site for all rocket activities; and covering the optics during high-risk times. Traditional concepts of lunar bases describe scenarios where components of the bases are landed on the lunar surface, one at a time, and then put together to form a complete stationary lunar habitat. Recently, some concepts have described the advantages of operating a mobile or 'roving' lunar base. Such a base vastly improves the exploration range from a primary lunar base. Roving bases would also allow the crew to first deploy, test, operationally certify, and then regularly maintain, service, and evolve long life-cycle facilities like observatories or other science payload platforms that are operated far apart from each other across the extraterrestrial surface. The Nomad Explorer is such a mobile lunar base. This paper describes the architectural program of the Nomad Explorer, its advantages over a stationary lunar base, and some of the embedded system concepts which help the roving base to speedily establish a global extraterrestrial infrastructure. A number of modular autonomous logistics landers will carry deployable or erectable payloads, service, and logistically resupply the Nomad Explorer at regular intercepts along the traverse. Starting with the deployment of science experiments and telecommunication networks, and the manned emplacement of a variety of remote outposts using a unique EVA Bell system that enhances manned EVA, the Nomad Explorer architecture suggests the capability for a rapid global development of the extraterrestrial body. The Moon and Mars are candidates for this 'mission oriented' strategy. The lunar case is emphasized in this paper. Author (revised)

Infrared emission of circumstellar dust was observed for almost one hundred T Tauri stars. This dust is interpreted to be part of a protoplanetary disk orbiting the central star. T Tauri stars are young stellar objects and evolve into solar type stars. Planets are believed to form in these disks. The spectral energy distribution of a disk depends on its temperature profile. Different disk regions emit at different wavelengths. The disk-star boundary layer is hot and emits H(alpha) radiation. Inner disk regions at around 1 AU with a temperature of a few hundred Kelvin can be probed in near infrared wavelength regimes. Outer disk regions at around 100 AU distance from the star are colder and emit far infrared and sub-millimeter radiation. Also, X-ray emission from the stellar surface can reveal information on disk properties. Emission from the stellar surface and the boundary layer may be shielded by circumstellar gas and dust. T Tauri stars with low H(alpha) emission, i.e. no boundary layer, show stronger X-ray emission than classical T Tauri stars, because the inner disk regions of weak emission-line T Tauri stars may be clear of material. In this paper, first ROSAT all sky survey results on the X-ray emission of T Tauri stars and correlations between X-ray luminosity and properties of T Tauri disks are presented. Due to atmospheric absorption, X-ray and most infrared observations cannot be carried out on Earth, but from Earth orbiting satellites (e.g. IRAS, ROSAT, ISO) or from lunar based observatories, which would have special advantages such as a stable environment. LEGAL REGIME OF HUMAN ACTIVITIES IN OUTER SPACE LAW **c84**

Carlo Golda *In* NASA. Marshall Space Flight Center, The Second Annual International Space University Alumni Conference Feb. 1994 p 66-75 (For primary document see N94-31425 09-12)

Avail: CASI HC A02/MF A02

Current developments in space activities increasingly involve the presence of humans on board spacecraft and, in the near future, on the Moon, on Mars, on board Space Stations, etc. With respect to these challenges, the political and legal issues connected to the status of astronauts are largely unclear and require a new doctrinal attention. In the same way, many legal and political questions remain open in the structure of future space crews: the need for international standards in the definition and training of astronauts, etc.; but, first of all, an international uniform legal definition of astronauts. Moreover, the legal structure for human life and operations in outer space can be a new and relevant paradigm for the definition of similar rules in all the situations and environments in which humans are involved in extreme frontiers. The present article starts from an overview on the existing legal and political definitions of 'astronauts', moving to the search of a more useful definition. This is followed by an analysis of the concrete problems created by human space activities, and the legal and political responses to them (the need for a code of conduct; the structure of the crew and the existing rules in the US and ex-USSR; the new legal theories on the argument; the definition and structure of a code of conduct; the next legal problems in fields such as privacy law, communications law, business law, criminal law, etc.). Today's mega-projects transcend the traditional trajectories traced within national and technological limitations. Powers unleashed by internationalization of initiatives, in for example space exploration and environmental protection, are arguably only temporarily suppressed by narrower national, economic, and professional disagreements as to how best they should be harnessed. While the world gets its act together there is time to develop the technologies of such supra-mega-project management

that will synergize truly diverse resources and smoothly mesh their interfaces. Such mega-projects and their management need to be realistically evaluated, when implementing such improvements. This paper examines current approaches to evaluating mega-projects and questions the validity of extrapolations to the supra-mega-projects of the future. Alternatives to improve such evaluations are proposed and described. Author

At present, Canada does not have enough scientists to be competitive in the global economy, which is rapidly changing from a reliance on natural resources and industry to information and technology. Space is the final frontier and it is a multidisciplinary endeavor. It requires a knowledge of science and math, as well as non-science areas such as architecture and law. Thus, it can attract a large number of students with a diverse range of interests and career goals. An overview is presented of the space education program designed by Canadian Alumni of the International Space University (CAISU) to encourage students to pursue studies and careers in science and technology and to improve science literacy in Canada.

The International Space University (ISU) was founded in 1987 to provide young space professionals with an international, multi-disciplinary approach to space education. The organization has held six 10-week summer sessions at which students from throughout the world have studied space. In 1995, ISU plans to begin a one-year Ph.D.-level program in space studies. This paper examines the educational goals of ISU in the context of current education trends. It discusses how trends toward internationalism and interdisciplinary studies are reshaping both education and the aerospace field. The tensions that exist between ISU's conflicting goals are discussed in the context of these prevailing currents. Author

CIM IN SPACE: CORPORATE INFORMATION MANAGEMENT (CIM) IMPLICATIONS FOR SPACE-BASED INFORMATION SYSTEMS Report, Aug. 1992 - Apr. 1993
Richard V. Mock Apr. 1993 48 p
(AD-A276882; NDU-ICAF-93-F22B) Avail: CASI HC A03/MF A01

This paper describes the DOD corporate information management (CIM) initiative, space forces, and space-based information systems used by the DOD. It then describes implications of CIM in the space industry. CIM is defined as a philosophy which has management and technical components. The CIM management philosophy includes concepts for standardization, system engineering, and the use of commercial systems and technology. The technical component uses the information engineering discipline to

improve business processes. The paper provides examples of the CIM management philosophy in operation as well as opportunities for CIM application. Information engineering is described as it applies to space-based information systems. The appendix includes an illustrative example of the integrated definition (IDEF) methodology applied to the tactical warning/attack assessment mission. DTIC

DOD SPACE BASED REQUIREMENTS: INCREASING DOD ACCESS TO SPACE Research Report, Aug. 1992 - Apr. 1993
Mary D. Kelly Apr. 1993 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276874; NDU-ICAF-93-S40) Avail: CASI HC A03

This paper concerns itself with an examination of DOD's need to expand space based capabilities to support military operations while focusing on the current launch environment as the greatest limiting factor to achieving expanded exploitation of space for DOD requirements. There is a discussion of existing launch systems, facilities, and capacity as well as current and experimental efforts in both payload and launch vehicle technology. A description of commercial practices regarding payload and launch vehicle utilization is contrasted with DOD's approach, and a projection of demand for launch access is compared against launch availability. An examination of certain technical, procedural, and acquisition alternatives for improving launch capacity is presented. This concludes with selected low cost recommendations for achieving the objective of increasing the ability to access space. DTIC

RESULTS FOR THE HYBRID LAMINAR FLOW CONTROL EXPERIMENT CONDUCTED IN THE NASA LANGLEY 8-FOOT TRANSONIC PRESSURE TUNNEL ON A 7-FOOT CHORD MODEL
Percy J. Bobbitt, James C. Ferris, William D. Harvey, and Suresh H. Goradia Mar. 1992 18 p
(RTOP 505-69-20-01)
(NASA-TM-107582; NAS 1.15:107582) Avail: CASI HC A03/MF A01

A description is given of the development of, and results from, the hybrid laminar flow control (HLFC) experiment conducted in the NASA LaRC 8 ft Transonic Pressure Tunnel on a 7 ft chord, 23 deg swept model. The methods/codes used to obtain the contours of the HLFC model surface and to define the suction requirements are outlined followed by a discussion of the model construction, suction system, instrumentation, and some example results from the wind tunnel tests. Included in the latter are the effects of Mach number, suction level, and the extent of suction. An assessment is also given of the effect of the wind tunnel environment on the suction requirements. The data show that, at or near the design Mach number, large extents of laminar flow can be achieved with suction mass flows over the first 25 percent, or less, of the chord. Top surface drag coefficients with suction extending from the near leading edge to 20 percent of the chord were approximately 40 percent lower than those obtained with no suction. The results indicate that HLFC can be designed for transonic speeds with lift and drag coefficients approaching those of LFC designs but with much smaller extents and levels of suction. AIR FORCE SPACE COMMAND SATELLITE ORBIT PREDICTOR USING PARALLEL VIRTUAL MACHINES M.S. Thesis
Susan K. Brewer Dec. 1993 104 p
(AD-A276316) Avail: CASI HC A06/MF A02

Parallel computing is the wave of the future. As the need for computational power increases, one processor is no longer sufficient to achieve the speed necessary to solve today's complex problems. The Air Force Space Command (AFSPACEOM) tracks approximately 8000 satellites daily; the model used by the AFSPACECOM, SGP4, (Simplified General Perturbation Model Four), has been the operational model since 1976. This thesis contains a detailed discussion of the mathematical theory of the SGP4 model. The tracking of a satellite requires extensive calculations. The satellite can be tracked more efficiently with parallel processing techniques. The principles developed are applicable to a Naval ship tracking multiple incoming threats; the increase in the speed of processing incoming data would result in personnel being informed faster and thus allow more time for better decisions during combat. Three parallel algorithms applied to SGP4 for implementations on a Parallel Virtual Machine (PVM) are developed. PVM is a small software package that allows a network of computer workstations to appear as a single large distributed-memory parallel computer. This thesis contains a description of several algorithms for the implementation on PVM to track satellites, the optimal number of workstations, and methods of distributing data. DTIC

GENERAL-RELATIVISTIC CELESTIAL MECHANICS. 4: THEORY OF SATELLITE MOTION
T. Damour (Observatoire de Paris, France.), M. Soffel (Tuebingen Univ., Germany.), and C. Xu (Tuebingen Univ., Germany.) Sep. 1993 36 p See also PB93-162527
(PB94-147782; IHES/P/93/47) Avail: CASI HC A03/MF A01

The basic equations needed for developing a complete relativistic theory of artificial Earth satellites are explicitly written down. These equations are given both in a local, geocentric frame and in the global, barycentric one. They are derived within our recently introduced general-relativistic celestial mechanics framework. Our approach is more satisfactory than previous ones, especially with regard to its consistency, completeness, and flexibility. In particular, the problem of representing the relativistic gravitational effects associated with the quadrupole and higher multipole moments of the moving Earth, which caused difficulties in several other approaches, is easily dealth with in our approach, thanks to the use of previously developed tools: definition of relativistic multipole moments and transformation theory between reference frames. With this last paper in a series, we hope to indicate the way of using our formalism in specific problems in applied celestial mechanics and astrometry. NTIS

ATTITUDE DYNAMICS OF SPINNING ROCKETS IN SPACE WITH INTERNAL MASS MOTION Ph.D. Thesis
Brian Douglas Staunton 1993 193 p
Avail: Univ. Microfilms Order No. DA9320374

Models of spinning rockets in space with internal mass motion are developed and analyzed. Three of the models use simple combinations of particle masses and springs to represent the internal mass motion. Two more models use fluid mechanical representations. One fluid model uses inviscid fluid assumptions and has no damping in the resulting equations, while the other includes viscous effects. The research is motivated by nutation instabilities observed in a class of orbit transfer vehicles. It is hypothesized that the instability mechanism relies on the motion of liquid inside the vehicle. A linear stability analysis is used to evaluate each model. Sets of model parameters which permit instabilities are identified. While all models can exhibit instabilities, it was not possible to confirm an instability for parameters consistent with the flight data. Two of the particle models reproduce some aspects of the data. Additional findings include the identification of an equivalent particle representation for one of the fluid models. The equations governing the third particle model closely resemble those of the fluid models. Also, a degenerate case of the viscous fluid model provides a new approach for representing a class of spacecraft nutation dampers. Dissert. Abstr.

A SIX DEGREE OF FREEDOM, PLUME-FUEL OPTIMAL TRAJECTORY PLANNER FOR SPACECRAFT PROXIMITY OPERATIONS USING AN A* NODE SEARCH M.S. Thesis - MIT
Mark Charles Jackson May 1994 147 p
(Contract NAS9-18426)
(NASA-CR-188285; NAS 1.26:188285; CSDL-T-1221) Copyright Avail: CASI HC A07/MF A02

Spacecraft proximity operations are complicated by the fact that exhaust plume impingement from the reaction control jets of space vehicles can cause structural damage, contamination of sensitive arrays and instruments,

or attitude misalignment during docking. The occurrence and effect of jet plume impingement can be reduced by planning approach trajectories with plume effects considered. An A* node search is used to find plume-fuel optimal trajectories through a discretized six dimensional attitude-translation space. A plume cost function which approximates jet plume isopressure envelopes is presented. The function is then applied to find relative costs for predictable 'trajectory altering' firings and unpredictable 'deadbanding' firings. Trajectory altering firings are calculated by running the spacecraft jet selection algorithm and summing the cost contribution from each jet fired. A 'deadbanding effects' function is defined and integrated to determine the potential for deadbanding impingement along candidate trajectories. Plume costs are weighed against fuel costs in finding the optimal solution. A* convergence speed is improved by solving approach trajectory problems in reverse time. Results are obtained on a high fidelity space shuttle/space station simulation. Trajectory following is accomplished by a six degree of freedom autopilot. Trajectories planned with, and without, plume costs are compared in terms of force applied to the target structure.

AEROSPACE TEST FACILITIES AT NASA LERC PLUMBROOK (Videotape)

Oct. 1992 Videotape: 10 min. 30 sec. playing time, in color, with sound (NASA-TM-109755; NONP-VT-94-9955) Avail: CASI VHS A01/BETA A22

An overview of the facilities and research being conducted at LeRC's Plumbrook field station is given. The video highlights four main structures and explains their uses. The Space Power Facility is the worlds largest space environment simulation chamber, where spacebound hardware is tested in simulations of the vacuum and extreme heat and cold of the space plasma environment. This facility was used to prepare Atlas 1 rockets to ferry CRRES into orbit; it will also be used to test space nuclear electric power generation systems. The Spacecraft Propulsion Research Facility allows rocket vehicles to be hot fired in a simulated space environment. In the Cryogenic Propellant Tank Facility, researchers are developing technology for storing and transferring liquid hydrogen in space. There is also a Hypersonic Wind Tunnel which can perform flow tests with winds up to Mach 7. CASI

DESIGN, PERFORMANCE, AND TEST STANDARDS FOR FLIGHT TERMINATION RECEIVERS/DECODERS. VOLUME 1: DESIGN AND PERFORMANCE REQUIREMENTS

Feb. 1994 23 p See also AD-A209644 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality (AD-A277245; RCC/RSG-313-94-Vol-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This standard provide the minimum electrical design and performance requirements for range safety flight termination receivers (FTR). The electrical design and performance requirements contained in this standard apply to all range safety FTR's. When the procurement specifications require the FTR's to have a special or peculiar feature that is not addressed in this standard, the design of that feature shall permit the feature to be tested.

ON-LINE PHYSICAL PARAMETER IDENTIFICATION AND ADAPTIVE CONTROL OF A LAUNCH VEHICLE Ph.D. Thesis

Brian Scott Keller 1993 203 p

Avail: Univ. Microfilms Order No. DA9317778

Physical parameter identification is useful in many applications, especially in aerospace where much analysis goes into developing accurate physical system models for control. A number of off-line physical parameter identification methods exist; however, the choice of on-line methods is more limited. On-line identification methods are required for adaptive control. New on-line physical parameter identification methods are developed in this work as motivated by the problem of launch vehicle adaptive control. Launch vehicles vary from launch to launch due to differences in payloads and fuel loading. Based on the known variations, launch vehicle control laws are reanalyzed and modified if necessary; this process is expensive and adds to recurring launch vehicle costs. This reanalysis is performed despite the fact that changes in the launch vehicle are relatively minor. A trustworthy adaptive control system could eliminate this expensive redesign cycle. An adaptive control system could also provide better performance than a controller redesigned off-line. However, adaptive control is still considered too risky to use with unstable systems, primarily due to limitations in the identification methods currently available for use in adaptive control. This problem is addressed with the development of new identification algorithms. A philosophy of identification is described which uses physical parameters for identification. A technique is developed to convert existing on-line methods to a form capable of identifying physical parameters. New methods include physical parameter versions of normalized least mean squares (NLMS), research least squares (RLS), extended least squares (ELS), recursive maximum likelihood (RML), and the extended Kalman filter (EKF). Compared to transfer function identification, physical parameter identification reduces the order of the problem and speeds up convergence. Compared to the extended Kalman filter, the new methods have a faster iteration time. The use of physical parameters also allows bounding based on expected parameter variations. The new identification methods are compared with existing methods and demonstrated in simulations of a two-mass/spring system, an OH-6A helicopter near hover, and the National Launch System 1.5-stage launch vehicle. Dissert. Abstr.

BASIC AND APPLIED STUDIES OF THE RAM ACCELERATOR AS A HYPERVELOCITY PROJECTILE LAUNCHER Annual Report, 1 Jul. 1992 - 30 Jun. 1993

Adam P. Bruckner and Carl Knowlen 10 Dec. 1993 98 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-92-J-0375)

(AD-A277392; AFOSR-94-0100TR) Avail: CASI HC A05

The potential of using ram accelerator technology for an impulsive launcher of autonomously guided interceptors, such as the LEAP, has been studied during this contract period. In addition, fundamental investigations on some of the engineering issues which must be addressed for enabling ram accelerator propulsive modes to operate at 4 km/sec have been undertaken. An experimental investigation of the gas dynamic limits of ram accelerator operation has demonstrated the existence of two distinct limiting mechanisms that must be accounted for when designing projectiles for these launchers. Other experiments were conducted to make detailed pressure measurements of the flow fields at the tube walls to study the effects of projectile canting. Results from this LEAP launcher study and the experimental investigations indicate that the ram accelerator technology is well suited for applications as a transportable launcher capable of meeting the needs of theater ballistic missile defense missions. SPACE FLIGHT RISK DATA COLLECTION AND ANALYSIS PROJECT: RISK AND RELIABILITY DATABASE Final Report
11 May 1994 137 p Prepared in cooperation with Science Applications International Corp., New York, NY
(Contract NASw-4776)
(NASA-CR-195879; NAS 1.26:195879) Avail: CASI HC A07/MF A02

The focus of the NASA 'Space Flight Risk Data Collection and Analysis' project was to acquire and evaluate space flight data with the express purpose of establishing a database containing measurements of specific risk assessment - reliability - availability - maintainability - supportability (RRAMS) parameters. The developed comprehensive RRAMS database will support the performance of future NASA and aerospace industry risk and reliability studies. One of the primary goals has been to acquire unprocessed information relating to the reliability and availability of launch vehicles and the subsystems and components thereof from the 45th Space Wing (formerly Eastern Space and Missile Command -ESMC) at Patrick Air Force Base. After evaluating and analyzing this information, it was encoded in terms of parameters pertinent to ascertaining reliability and availability statistics, and then assembled into an appropriate database structure. Coilguns have the ability to provide magnetic pressure to projectiles which results in near constant acceleration. However, to achieve this performance and control projectile hearing, significant constraints are placed on the design of the coils. We are developing coils to produce an effective projectile base pressure of 100 MPa as a step toward reaching base pressures of 200 MPa. The design uses a scalable technology applicable to the entire range of breech to muzzle coils of a multi-stage launcher. This paper presents the design of capacitor-driven coils for launching nominal 50 mm, 350 gram projectiles. Design criteria, constraints, mechanical stress analysis, launcher performance, and test results are discussed. DOE

Space Station Freedom will feature six large solar arrays, called solar array wings, built by Lockheed Missiles & Space Company under contract to Rockwell International, Rocketdyne Division. Solar cells are mounted on flexible substrate panels which are hinged together to form a 'blanket.' Each wing is comprised of two blankets supported by a central mast, producing approximately 32 kW of power at beginning-of-life. During launch, the blankets are fan-folded and compressed to 1.5 percent of their deployed length into containment boxes. This paper describes the main containment box mechanisms designed to protect, deploy, and retract the solar array blankets: the latch, blanket restraint, tension, and guidewire mechanisms. Author

Space Station Freedom requires the transmission of high power and signals through three different rotational interfaces. Roll ring technology was baselined by NASA for rotary joints to transfer up to 65.5 kW of power for 30 years at greater than 99 percent efficiency. Signal transfer requirements included MIL-STD-1553 data transmission and 4.5 MHz RS250A base and color video. A unique design for each rotary joint was developed and tested to accomplish power and signal transfer. An overview of roll ring technology is presented, followed by design requirements, hardware configuration, and test results. Author

(Contract NAS3-26285)
Avail: CASI HC A03/MF A04

Space and mass are at a premium on any space mission, and thus any machinery designed for space use should be lightweight and compact, without sacrificing strength. It is for this reason that NASA/LeRC contracted Unique Mobility Corporation to exploit their novel actuator designs to build a robot that would advance the present state of technology with respect to these requirements. Custom-designed motors are the key feature of this

robot. They are compact, high-performance dc brushless servo motors with a high pole count and low inductance, thus permitting high torque generation and rapid phase commutation. Using a custom-designed digital signal processor-based controller board, the pulse width modulation power amplifiers regulate the fast dynamics of the motor currents. In addition, the programmable digital signal processor (DSP) controller permits implementation of nonlinear compensation algorithms to account for motoring vs. regeneration, torque ripple, and back-EMF. As a result, the motors produce a high torque relative to their size and weight, and can do so with good torque regulation and acceptably high velocity saturation limits. This paper presents the Unique Mobility Corporation robot prototype: its actuators, its kinematic design, its control system, and its experimental characterization. Performance results, including saturation torques, saturation velocities and tracking accuracy tests are included. Author

DEVELOPMENT OF AN INTERCHANGEABLE END EFFECTOR MECHANISM FOR THE RANGER TELEROBOTIC VEHICLE **c37**
Robert Cohen and David L. Akin *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 79-89 (For primary document see N94-33291 09-15)
Avail: CASI HC A03/MF A04

The Ranger program at the Space Systems Laboratory (SSL) at the University of Maryland is a demonstration of an extremely low cost, space flight experiment. The Ranger vehicle is designed to perform teleoperated spacecraft maintenance. Completing the various tasks included in spacecraft maintenance requires several specific tools. This paper describes the Ranger interchangeable end effector mechanism (IEEM). Its design allows Ranger to change end effectors to utilize the appropriate tool for the various tasks. The Ranger vehicle is designed with four manipulators. A seven degree-of-freedom (DOF) grappling manipulator securely attaches the vehicle to the work site. A 6 DOF camera positioning manipulator allows the operator to position a stereo pair of video cameras for visual feedback. The two remaining manipulators are the 7 DOF dexterous arms. They are the primary means by which Ranger accomplishes its required tasks. At the end of each of these dexterous manipulators is an IEEM. This paper begins with a brief overview of the Space Systems Laboratory and the Ranger program. The constraints leading to the requirements for an IEEM are described. The following section then describes the design strategies and the down selection process resulting in two candidate designs, taper and pneumatic connector type. Next, the leading candidate design is described in detail, followed by a preliminary discussion of failure modes and planned testing. The paper concludes with a brief review and a section discussing future work. Author

LEVERAGING METAL MATRIX COMPOSITES TO REDUCE COSTS IN SPACE MECHANISMS **c24**
Ted Nye, Rex Claridge, and Jim Walker *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 129-134 (For primary document see N94-33291 09-15)
(Contracts F33615-90-C-3200; F33733-89-C-1011)
Avail: CASI HC A02/MF A04

Advanced metal matrix composites may be one of the most promising technologies for reducing cost in structural components without compromise to strength or stiffness. A microlight 12.50 N (2.81 lb), two-axis, solar array drive assembly (SADA) was made for the Advanced Materials Applications to Space Structures (AMASS) Program flight experiment. The SADA had both its inner and outer axis housings fabricated from silicon carbide particulate reinforced alumimun. Two versions of the housings were made. The first was machined from a solid billet of material. The second was plaster cast to a near net shape that required minimal finish machining. Both manufacturing methods were compared upon completion. Results showed a cost savings with the cast housing was possible for quantities greater than one and probable for quantities greater than two. For quantities approaching ten, casting resulted in a reduction factor of almost three in the cost per part. Author

DESIGN, DEVELOPMENT, AND TESTING OF A LIGHTWEIGHT OPTICAL SENSOR COVER SYSTEM **c18**
Mike Hurley and Scott Christiansen *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 135-140 (For primary document see N94-33291 09-15)
Avail: CASI HC A02/MF A04

This paper discusses aspects of the design, development, and testing of the sensor cover on the Clementine (DSPSE) spacecraft. Particular attention is given to defining the typically ambiguous issue of cleanliness. To characterize performance with respect to these requirements, a simple and effective method for testing prototype seals was developed. This testing was useful for comparing various types of seals as well as for providing information about achievable cleanliness levels. The results were invaluable input for defining a realistic final cleanliness requirement that satisfied everyone from mechanisms to sensor engineers. Balancing torque margins (reliability) versus cost and/or weight of the system can be significantly influenced by the choice of seal type. Several seal types are discussed in terms of both cleanliness and ease of implementation. These design issues influence the actuator selection and structural integrity of the door. The cover system designed and fabricated as described above was thoroughly tested both on a component level and on the Clementine system level. Testing included characterization, vibration, pyro-shock, life, and thermal/vacuum. The extensive testing identified problems early enough that they could be resolved prior to integration and launch. DESIGN, CHARACTERIZATION, AND CONTROL OF THE NASA THREE DEGREE OF FREEDOM REACTION COMPENSATION PLATFORM c18
Craig Birkhimer (Case Western Reserve Univ., Cleveland, OH.), Wyatt Newman (Case Western Reserve Univ., Cleveland, OH.), Benjamin Choi, and Charles Lawrence *In its* The 28th Aerospace Mechanisms Symposium May 1994 p 147-152 (For primary document see N94-33291 09-15)
Avail: CASI HC A02/MF A04

Increasing research is being done into industrial uses for the microgravity environment aboard orbiting space vehicles. However, there is some concern over the effects of reaction forces produced by moving objects, especially motors, robotic actuators, and astronauts. Reaction forces produced by the movement of these objects may manifest themselves as undesirable accelerations in the space vehicle making the vehicle unusable for microgravity applications. It is desirable to provide compensation for such forces using active means. This paper presents the design and experimental evaluation of the NASA three degree of freedom reaction compensation platform, a system designed to be a testbed for the feasibility of active attenuation of reaction forces caused by moving objects in a microgravity environment. Unique 'linear motors,' which convert electrical current directly into rectilinear force, are used in the platform design. The linear motors induce accelerations of the displacer inertias. These accelerations create reaction forces that may be controlled to counteract disturbance forces introduced to the platform. The stated project goal is to reduce reaction forces by 90 percent, or -20 dB. Description of the system hardware, characterization of the actuators and the composite system, and design of the software safety system and control software are included.

PIP PIN RELIABILITY AND DESIGN c37
Lane P. Skyles *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 153-158 (For primary document see N94-33291 09-15)
Avail: CASI HC A02/MF A04

Pip pins are used in many engineering applications. Of particular interest to the aerospace industry is their use in various mechanism designs. Many payloads that fly aboard our nation's Space Shuttle have at least one actuated mechanism. Often these mechanisms incorporate pip pins in their design in order to fasten interfacing parts or joints. Pip pins are most often used when an astronaut will have a direct interface with the mechanism. This interfacing can be done during Space Shuttle mission EVA's (ExtraVehicular Activity). The main reason for incorporating pip pins is convenience and their ability to provide a quick release for interfacing parts. However, there are some issues that must be taken into account when using them in a design. These issues include documented failures and quality control problems when using substandard pip pins. A history of pip pins as they relate to the aerospace industry as well as general design features is discussed.

INTELLIGENT CONTROL OF A MULTI-DEGREE-OF FREEDOM REACTION COMPENSATING PLATFORM SYSTEM USING FUZZY LOGIC c63
Benjamin B. Choi, Charles Lawrence, and Yueh-Jaw Lin *In its* The 28th Aerospace Mechanisms Symposium May 1994 p 159-165 (For primary document see N94-33291 09-15)
Avail: CASI HC A02/MF A04

This paper presents the development of a general-purpose fuzzy logic (FL) control methodology for isolating the external vibratory disturbances of space-based devices. According to the desired performance specifications, a full investigation regarding the development of an FL controller was done using different scenarios, such as variances of passive reaction-compensating components and external disturbance load. It was shown that the proposed FL controller is robust in that the FL-controlled system closely follows the prespecified ideal reference model. The comparative study also reveals that the FL-controlled system achieves significant improvement in reducing vibrations over passive systems.

HIGH PRECISION MOVING MAGNET CHOPPER FOR VARIABLE OPERATION CONDITIONS c74
Winfried Aicher and Manfred Schmid *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 167-181 (For primary document see N94-33291 09-15)
Avail: CASI HC A03/MF A04

In the context of an ESTEC technology contract, a Chopping Mechanism was developed and built with the Far Infrared and Submillimeter Telescope (FIRST) astronomy mission as a reference. The task of the mechanism is to tilt the subreflector of the telescope with an assumed mass of 2.5 kg about one chopping axis at nominal frequencies of up to 5 Hz and chopping angles of up to +/- 11.25 mrad with high efficiency (minimum time for position change). The chopping axis is required to run through the subreflector vertex. After performing a concept trade-off also considering the low operational temperatures in the 130 K range, a design using moving magnet actuators was found to be the favorite one. In addition, a bearing concept using flexible pivots was chosen to meet the high chopping accuracy required. With this approach, a very reliable design could be realized, since the actuators work without any mechanical contact between its moving and fixed parts, and the only bearings used are two flexible pivots supporting the subreflector mounting interface. The mechanism was completely built in titanium in a lightweight and stiff design. The moving magnet actuators were designed to meet the stringent requirements for minimum risetime (time necessary to move from one angular position to a new one) in the 20 msec range. The angular position and the corresponding chopping frequency as well can be arbitrarily selected by the user.

(Contract NAS5-29298)
Avail: CASI HC A03/MF A04

Two cover mechanisms were designed and developed for the Extreme Ultraviolet Explorer (EUVE) science payload to keep the EUVE telescope mirrors and detectors sealed from the atmospheric environment until the spacecraft was placed into orbit. There were four telescope front covers and seven motorized detector covers on the EUVE science payload. The EUVE satellite was launched into orbit in June 1992 and all the covers

operated successfully after launch. This success can be attributed to high design margins and extensive testing at each level of assembly. This paper described the design of the telescope front covers and the motorized detector covers. This paper also discusses some of the many design considerations and modifications made as performance and reliability problems became apparent from each phase of testing. Author

A COMPARISON OF THE PERFORMANCE OF SOLID AND LIQUID LUBRICANTS IN OSCILLATING SPACECRAFT BALL BEARINGS **c27**

S. Gill *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 229-244 (For primary document see N94-33291 09-15)

Avail: CASI HC A03/MF A04

The European Space Tribology Laboratory (ESTL) has been engaged in a program to compare the performance of oscillating ball bearings when lubricated by a number of space lubricants, both liquid and solid. The results have shown that mean torque levels are increased by up to a factor of five above the normal running torque, and that often torque peaks of even greater magnitudes are present at the ends of travel. It is believed that these effects are caused by a build-up of compacted debris in the contact zone, thus reducing the ball/race conformity ratio. Author (revised)

This paper describes the development of dry-lubricated linear bearings for use on the Michelson interferometer for passive atmospheric sounding (MIPAS). Two candidate bearing systems were developed and tested. In the first, use was made of linear roller (needle) bearings equipped with a pulley-and-cable arrangement to prevent cage drift and to minimize roller slip. The second design was of a roller-guided bearing system in which guidance was provided by all bearings rolling along guide rods. The paper focuses on the development of these linear bearings systems and describes the approach taken in terms of bearing design, lubrication methods, screening programs, and thermal-vacuum testing. Development difficulties are highlighted and the solutions ultimately adopted are described. Author (revised)

THE PRELIMINARY EVALUATION OF LIQUID LUBRICANTS FOR SPACE APPLICATIONS BY VACUUM TRIBOMETRY **c27**

W. R. Jones, Jr., S. V. Pepper, P. Herrera-Fierro, D. Feuchter, T. J. Toddy, D. T. Jayne, D. R. Wheeler, P. B. Abel, E. Kingsbury, and W. Morales et al *In its* The 28th Aerospace Mechanisms Symposium May 1994 p 265-277 (For primary document see N94-33291 09-15)

Avail: CASI HC A03/MF A04

Four different vacuum tribometers for the evaluation of liquid lubricants for space applications are described. These range from simple ball-on-flat sliders with maximum in-situ control and surface characterization to an instrument bearing apparatus having no in-situ characterization. Thus, the former provides an abundance of surface chemical information but is not particularly simulative of most triboelements. On the other hand, the instrument bearing apparatus is completely simulative, but only allows post-mortem surface chemical information. Two other devices, a four-ball apparatus and a ball-on-plate tribometer, provide varying degrees of surface chemical information and tribo-simulation. Examples of data from each device are presented. DESIGN OF A HIGH-SPEED RELIABLE BALL BEARING **c37**

Herbert B. Singer and Erik Gelotte *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 279-283 (For primary document see N94-33291 09-15)

Avail: CASI HC A01/MF A04

A high-speed, reliable ball bearing has been designed for at least fifteen years of operation in space effectors, MWA's, and RWA's. Advanced bearing concepts have been used in this design, such as: no ball retainer, which eliminates all retainer-related problems; an external lubricazing system that will supply the lubricant at a specified flow rate; and a cartridge assembly that will allow the instrument user to purchase a ready to use bearing assembly, with lubricator. Currently, two assemblies are on life test at 12,000 RPM and have accumulated over 20,000 hours each, with consistent low-torque losses. This paper will describe each of the salient features. MSAT BOOM JOINT TESTING AND LOAD ABSORBER DESIGN **c37**

D. H. Klinker, K. Shuey, and D. R. St.Clair *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 285-302 (For primary document see N94-33291 09-15)

Avail: CASI HC A03/MF A04

Through a series of component and system-level tests, the torque margin for the MSAT booms is being determined. The verification process has yielded a number of results and lessons that can be applied to many other types of deployable spacecraft mechanisms. The MSAT load absorber has proven to be an effective way to provide high energy dissipation using crushable honeycomb. Using two stages of crushable honeycomb and a fusible link, a complex crush load profile has been designed and implemented. The design features of the load absorber lend themselves to use in other spacecraft applications. Author (revised)

SPECIAL TEST EQUIPMENT AND FIXTURING FOR MSAT REFLECTOR ASSEMBLY ALIGNMENT **c37**

Jeffrey A. Young, Michael R. Zinn, and David R. McCarten *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 303-322 (For primary document see N94-33291 09-15)

Avail: CASI HC A03/MF A04

The MSAT Reflector Assembly is a state of the art subsystem for Mobile Satellite (MSAT), a geosynchronous-based commercial mobile telecommunication satellite program serving North America. The Reflector Assembly consisted of a deployable, three-hinge, folding-segment Boom, deployable 5.7 x 5.3-meter 16-rib Wrap-Rib Reflector, and a Reflector Pointing Mechanism (RPM). The MSAT spacecraft was based on a Hughes HS601 spacecraft bus carrying two Reflector Assemblies independently dedicated for L-band transmit and receive operations. Lockheed Missiles and Space Company (LMSC) designed and built the Reflector Assembly for MSAT under contract to SPAR Aerospace Ltd. Two MSAT satellites were built jointly by SPAR Aerospace Ltd. and Hughes Space and Communications Co. for this program, the first scheduled for launch in 1994. When scaled for wavelength, the assembly and alignment requirements for the Reflector Assembly were in many instances equivalent to or exceeded that of a diffraction-limited visible light optical system. Combined with logistical constraints inherent to large, compliant, lightweight structures; 'bolt-on' alignment; and remote, indirect spacecraft access; the technical challenges were formidable. This document describes the alignment methods, the special test equipment, and fixturing for Reflector Assembly assembly and alignment. Author

DEPLOYABLE AND RETRACTABLE TELESCOPING TUBULAR STRUCTURE DEVELOPMENT **c37**
M. W. Thomson *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 323-338 (For primary document see N94-33291 09-15)
Avail: CASI HC A03/MF A04

A new deployable and retractable telescoping boom capable of high deployed stiffness and strength is described. Deployment and retraction functions are controlled by simple, reliable, and fail-safe latches between the tubular segments. The latch and a BI-STEM (Storable Tubular Extendible Member) actuator work together to eliminate the need for the segments to overlap when deployed. This yields an unusually lightweight boom and compact launch configuration. An aluminum space-flight prototype with three joints displays zero structural deadband, low hysteresis, and high damping. The development approach and difficulties are discussed. Test results provide a joint model for sizing flight booms of any diameter and length. Author

LESSONS LEARNED FROM SELECTING AND TESTING SPACEFLIGHT POTENTIOMETERS **c19**
T. Iskenderian *In* NASA. Lewis Research Center, The 28th Aerospace Mechanisms Symposium May 1994 p 339-358 (For primary document see N94-33291 09-15)
Avail: CASI HC A03/MF A04

A solar array drive (SAD) was designed for operation on the TOPEX/POSEIDON spacecraft that was launched in August, 1992. The experience gained in selecting, specifying, testing to failure, and redesigning its position sensor produced valuable lessons for future component selection and qualification. Issues of spaceflight heritage, cost/benefit/risk assessment, and component specification are addressed. It was found that costly schedule and budget overruns may have been avoided if the capability of the candidate sensors to meet requirements had been more critically examined prior to freezing the design. The use of engineering models and early qualification tests is also recommended. Author

This paper presents general insight into the design and implementation of heaters as used in actuating mechanisms for spacecraft. Problems and considerations that were encountered during development of the Deep Space Probe and Science Experiment (DSPSE) solar array release mechanism are discussed. Obstacles included large expected fluctuations in ambient temperature, variations in voltage supply levels outgassing concerns, heater circuit design, materials selection, and power control options. Successful resolution of these issues helped to establish a methodology which can be applied to many of the heater design challenges found in thermally actuated mechanisms. Author

Avail: CASI HC A03/MF A04

A payload holddown and release mechanism, designated the Model 1172, was designed and built at G&H Technology during the winter of 1992/1993. The mechanism is able to restrain and release a 45-pound payload with minimal tipoff. The payload is held in place by a stainless steel band and released using electrically triggered non-explosive actuators. These actuators provide reliable operation with negligible shock and no special handling requirements. The performance of the mechanism was demonstrated in two flight tests. Data showed pitch and yaw tipoff rates of less than 0.07 radian (4 degree) per second. The Model 1172 design is an efficient replacement for conventional payload deployment devices, especially where low transmitted shock is required. Author

The objective of the ARTS program was to develop lighter and less expensive spacecraft ordnance and release systems that answer to the requirements of a wide variety of spacecraft applications. These improvements were to be evaluated at the spacecraft system level, as it was determined that there were substantial system-level costs associated with the present ordnance and release subsystems. New, better devices were to be developed, then flight qualified, then integrated into a flight experiment in order to prove the reliability required for their subsequent use on high-reliability spacecraft. The secondary goal of the program was to quantify the system-level benefits of these new subsystems based upon the development program results. Three non-explosive release mechanisms and one laser-diode-based ordnance system were qualified under the program. The release devices being developed were required to release high preloads because it is easier to scale down a release mechanism than to scale it up. The laser initiator developed was required to be a direct replacement for NASA Standard Initiators, since these are the most common initiator in use presently. The program began in October, 1991, with completion of the flight experiment scheduled for February, 1994. This paper provides an overview of the ARTS program, discusses the benefits of using the ARTS components, introduces the new components, compares them with conventional systems and each other, and provides recommendations on how best to implement them. As a precursor to future manned missions to the moon, an inexpensive, unmanned vehicle that could carry small, scientific payloads to the lunar surface was studied by NASA. The vehicle, called the Common Lunar Lander, required extremely optimized structural systems to increase the potential payload mass. A lightweight energy-absorbing system (LAGFEAS), which also acts as a landing load-limiter was designed to help achieve this optimized structure. Since the versatile and easily tailored system is a load-limiter, it allowed for the structure to be designed independently of the ever-changing landing energy predictions. This paper describes the LAGFEAS system and preliminary verification testing performed at NASA's Johnson Space Center for the Common Lunar Lander program. Author

THEORETICAL BASIS FOR STATE VECTOR COMPARISON, RELATIVE POSITION DISPLAY, AND RELATIVE POSITION/RENDEZVOUS PREDICTION M.S. Thesis
Lester B. Makepeace, III Dec. 1993 94 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277216) Avail: CASI HC A05

This thesis outlines the theoretical underpinnings used for the software designed to meet Detailed Technical Objectives 700-6 and 700-7 for the Space Shuttle Discovery mission STS-51. The primary goal was to compare state vector information produced by an onboard GPS receiver and Discovery's computers and provide real time display of the results. Because state vector information for the ORFEUS/SPAS payload was also available, relative position and rendezvous information between Discovery and ORFEUS/SPAS was made possible. Analysis of the various state vectors was used to produce a graphical display, in an operationally meaningful format, to the flight crew of Discovery. DTIC

ACCESS TO SPACE: THE SPACE SHUTTLE'S EVOLVING ROLEE Report, Aug. 1992 - Apr. 1993
Steven R. Duttry Apr. 1993 44 p
(AD-A276785; NDU-ICAF-93-F27) Avail: CASI HC A03/MF A01

Access to space is of extreme importance to our nation and the world. Military, civil, and commercial space activities all depend on reliable space transportation systems for access to space at a reasonable cost. The Space Transportation System or Space Shuttle was originally planned to provide transportation to and from a manned Earth-orbiting space station. To justify the development and operations costs, the Space Shuttle took on other space transportation requirements to include DoD, civil, and a growing commercial launch market. This research paper or case study examines the evolving role of the Space Shuttle as our nation's means of accessing space. The case study includes a review of the events leading to the development of the Space Shuttle, identifies some of the key players in the decision-making process, examines alternatives developed to mitigate the risks associated with sole reliance on the Space Shuttle, and highlights the impacts of this national space policy following the Challenger accident. COMPUTATIONAL METHODS FOR FRICTIONAL CONTACT WITH APPLICATIONS TO THE SPACE SHUTTLE ORBITER NOSE-GEAR TIRE Ph.D. Thesis
John A. Tanner 1993 210 p
Avail: Univ. Microfilms Order No. DA9313716

A computational procedure has been presented for the solution of frictional contact problems for aircraft tires. The Space Shuttle nose gear tire was modeled using a two-dimensional laminated anisotropic shell theory with the effects of variation in material and geometric parameters, transverse-shear deformation, and geometric nonlinearities included. The contact conditions were incorporated into the formulation by using a perturbed Lagrangian approach with the fundamental unknowns consisting of the stress resultants, the generalized displacements, and the Lagrange multipliers associated with the contact and friction conditions. The contact-friction algorithm was based on a modified Coulomb friction law. The elemental arrays were obtained by using a modified two-field, mixed variational principle. The modification consisted of augmenting the functional of that principle by two terms: the Lagrange multiplier vector associated with nodal normal and tangential contact load intensities and a regularization term which was quadratic in the Lagrange multiplier vector. Experimental measurements were made to define the response of the Space Shuttle nose-gear tire to inflation pressure loads and to combined inflation pressure loads and static normal loads against a rigid flat plate. These experimental results describe meridional growth of the tire cross section due to inflation loading, the static load-deflection characteristics of the tire, the geometry of the tire footprint under the static loading conditions, and the normal and tangential load intensity distributions in the tire footprint for the various static vertical loading conditions. Numerical results were obtained for the Space Shuttle nose-gear tire subjected to inflation pressure loads and combined inflation pressure and contact loads against a rigid flat plate. Comparisons were made between the experimental measurements and the numerical results. Dissert. Abstr.

ADVANCED TRANSPORTATION SYSTEM STUDY: MANNED LAUNCH VEHICLE CONCEPTS FOR TWO WAY TRANSPORTATION SYSTEM PAYLOADS TO LEO Final Report, 15 Feb. 1992 - 15 Dec. 1993
James B. Duffy 1993 589 p
(Contract NAS8-39207)
(NASA-CR-193951; NAS 1.26:193951; SSD93M0025-1) Avail: CASI HC A25/MF A06

The purpose of the Advanced Transportation System Study (ATSS) task area 1 study effort is to examine manned launch vehicle booster concepts and two-way cargo transfer and return vehicle concepts to determine which of the many proposed concepts best meets NASA's needs for two-way transportation to low earth orbit. The study identified specific configurations of the normally unmanned, expendable launch vehicles (such as the National Launch System family) necessary to fly manned payloads. These launch vehicle configurations were then analyzed to determine the integrated booster/spacecraft performance, operations, reliability, and cost characteristics for the payload delivery and return mission. Design impacts to the expendable launch vehicles which would be required to perform the manned payload delivery mission were also identified. These impacts included the implications of applying NASA's man-rating requirements, as well as any mission or payload unique impacts. The booster concepts evaluated included the National Launch System (NLS) family of expendable vehicles and several variations of the NLS reference configurations to deliver larger manned payload concepts (such as the crew logistics vehicle (CLV) proposed by NASA JSC). Advanced, clean sheet concepts such as an F-1A engine derived liquid rocket booster (LRB), the single stage to orbit rocket, and a NASP-derived aerospace plane were also included in the study effort. Existing expendable launch vehicles such as the Titan 4, Ariane 5, Energia, and Proton were also examined. Although several manned payload concepts were considered in the analyses, the reference manned payload was the NASA Langley Research Center's HL-20 version of the personnel launch system (PLS). A scaled up version of the PLS for combined crew/cargo delivery capability, the HL-42 configuration, was also included in the analyses of cargo transfer and return vehicle (CTRV) booster concepts. In addition to strictly manned payloads, two-way cargo transportation systems (CTRV's) were also examined. The study provided detailed design and analysis of the performance, reliability, and operations of these concepts. The study analyzed these concepts as unique systems and also analyzed several combined CTRV/booster configurations as integrated launch systems (such as for launch abort analyses). Included in the set of CTRV concepts analyzed were the medium CTRV, the integral CTRV (in both a pressurized and unpressurized configuration), the winged CTRV, and an attached cargo carrier for the PLS system known as the PLS caboose. USING MONTE CARLO TECHNIQUES AND PARALLEL PROCESSING FOR DEBRIS HAZARD ANALYSIS OF ROCKET SYSTEMS
R. A. LaFarge Feb. 1994 56 p
(Contract DE-AC04-94AL-85000)
(DE94-007250; SAND-93-2073) Avail: CASI HC A04/MF A01

Sandia National Laboratories has been involved with rocket systems for many years. Some of these systems have carried high explosive onboard, while others have had FTS for destruction purposes whenever a potential hazard is detected. Recently, Sandia has also been involved with flight tests in which a target vehicle is intentionally destroyed by a projectile. Such endeavors always raise questions about the safety of personnel and the environment in the event of a premature detonation of the explosive or an activation of the FTS, as well as intentional vehicle destruction. Previous attempts to investigate fragmentation hazards for similar configurations have analyzed fragment size and shape in detail but have computed only a limited number of trajectories to determine the probabilities of impact and casualty expectations. A computer program SAFETIE has been written in support of various SNL flight experiments to compute better approximations of the hazards. SAFETIE uses the AMEER trajectory computer code and the Engineering Sciences Center LAN of Sun workstations to determine more realistically the probability of impact for an arbitrary number of exclusion areas. The various debris generation models are described. DOE

PHASE-LOCK ROLL CONTROL OF INERTIALLY POINTING SPACECRAFT Ph.D. Thesis
Jeffrey Roger Crerie 1993 203 p
Avail: Univ. Microfilms Order No. DA9326452

The spacecraft which houses the Stanford Relativity Gyroscope Experiment (GP-B) is designed to roll with a 10 minute period about its pointing axis. A precise measurement of roll phase is needed to demodulate the two relativity effects being measured by GP-B. Optimally, the spacecraft will be flown with no rotating machinery on board, so it is desired to control roll without the use of conventional rate gyros. A new technique has been devised to achieve highly accurate roll control without a rate gyro. This is done by employing one or more slit star sensors which rotate with the spacecraft, and correlate their output with a known reference to produce a measurement of roll offset. The technique developed to control roll phase and rate mimics those used in pseudorandom noise telecommunication. The algorithm regards the intensity pattern of the surrounding star field as pseudorandom noise which repeats every 360 degrees, and sets up a 'phase-locked' loop to align the pattern with a stored reference pattern. Single-axis simulations confirm that such a device, combined with a steady-state Kalman estimator, can control roll position to an accuracy of 20 arcsec RMS, and roll rate to an accuracy of 0.92 arcsec/sec RMS, even when the star sensor output and reference values are encoded with one bit and disturbance torques are very large. A hardware simulation was useful in demonstrating the capabilities of this simple, low-cost system and in determining the noise characteristics of the combined sensor and electronics. A laboratory-based hardware simulation was achieved by modeling the intensities of stars located within the relevant band on a NeXT graphics monitor and then animating this image at a rate governed by the plant dynamics model. This 'scrolling star field' is imaged onto a high-speed, high-sensitivity photodiode whose output undergoes a one-bit discretization before correlation with the stored reference. The correlation scheme, subsequent filtering, and updates to the dynamics model all occur within the Motorola DSP56001 which comes installed on the NeXT computer. This hardware-in-the-loop test validates the theory previously described.

ADAPTIVE NONLINEAR CONTROL OF SPACECRAFT Ph.D. Thesis
Jyh-Jong Sheen 1993 139 p
Avail: Univ. Microfilms Order No. DA9323547

The feedback linearization technique is applied to the problem of spacecraft attitude control and momentum management with control moment gyros (CMG's). The feedback linearization consists of a coordinate transformation and a nonlinear state feedback to cancel the nonlinear dynamics. These two steps result in a linear system equivalent to the original nonlinear system. Pole placement techniques are then used to place the closed-loop poles. Stability in a neighborhood of a controllable torque equilibrium attitude (TEA) is guaranteed. The nonlinear control law developed via feedback linearization is simplified by a standard linearization technique. The linearized nonlinear controller provides a natural way to select control gains for the multiple-input, multiple-output spacecraft system. Simulation results using the linearized nonlinear controller show good performance relative to the nonlinear controller in the neighborhood of the TEA. A chief limitation of the feedback linearization technique is that it requires an exact cancellation of nonlinear terms in order to obtain linear input-output behavior. As a consequence, if there are uncertainties in parameters, the cancellation is no longer exact and the linear behavior can not be obtained. Adaptive control of linearizable systems is used to overcome this restriction and to achieve asymptotic linear behavior. Two adaptive control laws are developed. One is based on a tracking error model. The other utilizes both the tracking error and the prediction error. The convergence properties of the adaptive algorithms are proved. The adaptive nonlinear control laws are applied to the problem of spacecraft attitude control and momentum management, assuming uncertainties in the spacecraft principal inertias. The combined tracking and prediction-error based adaptive controller is shown to have improvement on the performance of the tracking-error based adaptive controller. Both algorithms are also tested under the circumstance of unmodeled dynamics with the cross-product inertias neglected. The adaptive tracking algorithm results in better estimation errors and state response. Dissert. Abstr.

THE INFLUENCE OF THE DEORBIT-BURN MANOEUVRE ON THE FOOTPRINT OF A RE-ENTRY CAPSULE
E. Mooij Jul. 1993 96 p

(LR-727; ISBN-9-06-275906-8; ETN-94-96137) Copyright Avail: CASI HC A05/MF A01

The implementation of the deorbit-burn maneuver in the entry simulation software START (Simulation Tool for Atmospheric Re-entry Trajectories) is presented. Two models are derived. The first model assumes an impulsive Delta(v), in which the (inertial) velocity change is vectorially added to the velocity of the spacecraft. The second model takes the finite time of the maneuver into account and the maneuver is a thrusted one. The two models are evaluated and the differences in flight time, entry conditions and entry path are shown to be substantial. The impulsive model is used to do a sensitivity analysis for the Assured Crew Return Vehicle (ACRV). The influence of initial height, magnitude and direction of the burn on the footprint of the vehicle is shown and discussed. ESA

CHAOTIC ATTITUDE MOTION OF SATELLITES IN THE CENTRAL GRAVITATIONAL FIELD Ph.D. Thesis
Xiaohua Tong 1992 176 p
(ISBN-0-315-78768-6) Avail: Univ. Microfilms Order No. DANN78768

New developments in nonlinear dynamics in the last two decades, especially chaos theory, make it possible to study various dynamic phenomena of nonlinear systems. In the present thesis, the nonlinear attitude motion of a satellite consisting of a single rigid body, or of two rigid bodies in gyrostat configuration, in a central gravitational field, on a circular or an elliptic orbit, is studied with particular attention given to the understanding of long-time dynamic behavior for a wide range of parameters. For the attitude motion of satellites in their orbital plane, it is shown that there exists chaotic motion for satellites with or without internal damping, in an elliptic orbit. It is shown that the system which describes the dynamic behavior of satellites without internal damping is nonintegrable. Thus chaotic motion and regular motion coexist. The connection between periodic motion and chaotic motion for satellites without internal damping is investigated numerically by studying the local bifurcations of periods motion. For satellites with internal damping, analytic criteria based on the Melnikov method are presented to determine whether chaotic motion might occur, and to reveal the connection between periodic motion and chaotic motion. The transition from periodic motion to chaotic motion for satellites with internal damping is studied by three means: phase planes, Poincare maps, and Lyapunov exponents. For the attitude motion of spinning axisymmetric single-body satellites or spinning axisymmetric gyrostat satellites without internal damping in a circular orbit, the Hamiltonians for the attitude motion are established and then used to reveal the characteristics of different types of motion, i.e. periodic motion, quasiperiodic motion, and chaotic motion. It is shown that except for the integrable cases where the attitude motion is either confined to small attitude angles around the equilibrium attitude positions, or the satellites are free of external torques, regular (periodic and quasiperiodic) and chaotic motion coexist depending on initial conditions, and the transition between the two types of motion is complicated. The global characteristics of the chaotic motion are obtained via the Poincare map technique. It is found that for gyrostat satellites with the axes of symmetry of the platform and the rotor coinciding, the rotor has a significant effect not only on the stability of equilibrium attitude positions, but also on the general dynamic behavior of the motion, e.g. a chaotic motion will become more and more regular as the spin velocity of the rotor increases. This is obviously of great importance in the design of gyrostat satellites.

TESTING FOR PREFERRED-FRAME EFFECTS IN GRAVITY WITH ARTIFICIAL EARTH SATELLITES
T. Damour (Observatoire de Paris, France.) and G. Esposito-Farese (Centre National de la Recherche Scientifique, Marseilles, France.) Oct. 1993 30 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148459; IHES/P/93/48) Avail: CASI HC A03

As gravity is a long-range force, one might a priori expect the Universe's global matter distribution to select a preferred rest frame for local gravitational physics. At the post-Newtonian approximation, two parameters suffice to describe the phenomenology of preferred-frame effects. It is pointed out that the observation of particular orbits of artificial Earth satellites has the potential of improving the alpha sub 1 limits by a couple of orders of magnitude, thanks to the appearance of small divisors which enhance the corresponding preferred-frame effects. There is a discrete set of inclinations which lead to arbitrarily small divisors, while, among zero-inclination (equatorial) orbits, geostationary ones are near optimal. The main alpha sub 1 - induced effects are: (1) a complex secular evolution of the eccentricity vector of the orbit, describable as the vectorial sum of several independent rotations; and (2) a yearly oscillation in the longitude of the satellite.

ELECTRICAL PROPERTIES OF DOUBLE LAYER DIELECTRIC STRUCTURES FOR SPACE TECHNOLOGY Ph.D. Thesis
Anqing Lian Apr. 1993 160 p
(ISBN-0-315-86547-4; CTN-94-61211) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Polymeric films such as polyimide (PI) and polyethylene terephthalate (PET) are used in space technology as thermal blankets. Thin SiO2 and SiN coatings plasma deposited onto PI and PET surfaces were proposed to protect the blanket materials against the space environment. The electrical properties of this kind of dual layer dielectric structure were investigated to understand the mechanisms for suppressing charge accumulation and flashover. Bulk and surface electrical conductivities of thin single-layer PI and PET samples and of the dual layer SiO2 and SiN combinations with PI and PET were measured in a range of applied electrical fields. The capacitance voltage (CV) technique was used for analyzing charge transport and distribution in the structures. The electric current in the bulk of the SiO2/PI and SiN/PI samples was found to depend on the polarity of the electric field. Other samples did not exhibit any such polarity effect. The polarity dependence is attributed to charge trapping at the PI/plasma deposit interface. The CV characteristics of the Al-PI-SiO2-Si structure confirm that charges which can modify the local electric field can be trapped near the interface. A model is proposed to interpret the properties of the currents in dual layer structures. This model can semi-quantitatively explain all the observed results. Author (CISTI)

PRE-FLIGHT TESTING OF THERMOELECTRIC QUARTZ CRYSTAL MICROBALANCES (TQCM) FOR MIDCOURSE SPACE EXPERIMENT (MSX) SPACECRAFT Final Report, 15 Dec. 1992 - 10 May 1993
R. J. Bryson, F. L. Seiber, W. T. Bertrand, J. H. Jones, and B. E. Wood Feb. 1994 98 p Prepared in cooperation with Calspan Corp., Arnold AFS, TN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277054; AEDC-TR-93-24) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Testing of six Midcourse Space Experiment (MSX) satellite thermoelectric quartz crystal microbalances (TQCM) was completed. These will be used to monitor contamination at various locations on the spacecraft. The tests included a 3-week drift test, power on/off tests; temperature cycling of TQCM crystals, mounting base, and flight electronics box; and deposition of carbon dioxide gas. The data obtained will be used for analyzing MSX satellite flight contamination data. DTIC

This paper documents a baseline assessment of the Satellite Communications Industry which is defined as companies that do the following: (1) build communications satellites; (2) build communications satellite earth terminals; and (3) provide satellite communications services. The assessment uses the standard analysis tools of Structure, Conduct, and Performance to evaluate the current health of the industry and includes a discussion of the outlook for the industry, the industry's strategy for survival, and government policy recommendations. Modern space surveillance requires fast and accurate orbit predictions for myriads of objects in a broad range of Earth orbits. Conventional Special Perturbations orbit propagators, based on numerical integration of the osculating equations of motion, are accurate but extremely slow. Conventional General Perturbations orbit propagators, based on fully analytical theories like those of Brouwer, are faster but contain large errors due to inherent approximations in the theories. New orbit generators based on Semianalytic Satellite Theory have been able to approach the accuracy of Special Perturbations propagators and the speed of General Perturbations propagators. Semianalytic Satellite Theory has been originated by P.J. Cefola and his colleagues, but the theory is scattered throughout the published and unpublished literature. In this document the theory is simplified, assembled, unified, and extended. DTIC

The angular momentum of a free-flying multibody system in space is a conserved quantity. This conservation law acts as a nonholonomic constraint and manifests itself when cyclic motion of the articulated joints of an on board manipulator produces a net change in the orientation of the whole system. This poses two important and coupled problems: (1) the motion planning problem of the manipulator for attitude reorientation of the space structure using internal motion of the joints, and (2) planning the manipulator joint trajectories that produce repeatable motion of all the configuration variables. We have adopted a surface integral approach to come up with algorithms for these nonholonomic motion planning problems. DTIC

DYNAMICS AND CONTROL OF ORBITING FLEXIBLE SYSTEMS: A FORMULATION WITH APPLICATIONS Ph.D. Thesis
Chun-Ki Alfred Ng 1992 312 p
(ISBN-0-315-75390-0) Avail: Univ. Microfilms Order No. DANN75390

A relatively general formulation for studying the nonlinear dynamics and control of spacecraft with interconnected flexible members in a tree-type topology is developed. The distinctive features of the formulation include the following: (1) It is applicable to a large class of present and future spacecraft with flexible beam and plate type appendages, arbitrary in number and orientation. (2) The members are free to undergo predefined slewing maneuvers to facilitate modelling of sun tracking solar panels and large angle maneuvers of space based robots. (3) Solar radiation induced thermal deformations of flexible members are incorporated in the study. (4) The governing equations of motion are highly nonlinear, nonautonomous and coupled. They are programmed in a modular fashion to help isolate the effects of flexibility, librational motion, thermal deformations, slewing maneuvers, shifting center of mass, higher modes, initial conditions, etc. The first chapter of the thesis presents a general background to the subject and a brief review of the relevant literature on multibody dynamics. This is followed by the kinematics and kinetics of the problem leading to the Lagrangian equations of motion. The third chapter focuses on methodology and development of the computer code suitable for parametric dynamical study and control. Next versatility of the general formulation is illustrated through the analysis of five spacecraft configurations of contemporary interest the next generation of multi-purpose communications spacecraft represented by the INdian SATellite II (IN-SAT II): the First Element Launch (FEL) and the Permanently Manned Configuration (PMC) of the proposed Space Station Freedom; the Mobile Servicing System (MSS) to be developed by Canada for operation on the Space Station; and the Space Flyer Unit (SFU) to be launched by Japan in mid-nineties. In the FEL study, the attention is directed towards interactions between the librational and vibrational dynamics. During the PMC investigation, effects of the thermal deformation and orbital eccentricity are introduced and the microgravity environment around the station center of mass explored. The MSS study assesses pointing errors arising from inplane and out-of-plane maneuvers of the robotic arms. The SFU represents a challenging configuration to assess deployment and retrieval dynamics associated with a solar array. Parameters considered here include symmetry, orientation, and duration of the deployment/retrieval maneuvers. Results of the dynamical study clearly shows that, under critical combinations of parameters, the systems can become unstable. Obviously, the next logical step is to explore control strategies to restore equilibrium. To that end, feasibility of the nonlinear control based on the Feedback Linearization Technique (FLT) is explored with reference to the INSAT II and the MSS. Results show the procedure to be quite promising in controlling the INSAT II over a range of disturbances, including the thermal effects. Application of the control to the MSS reduced the pointing error induced by robotic arm maneuvers significantly. The amount of information obtained through a planned parametric analysis of the system dynamics and control is indeed enormous. More significant results are summarized in the concluding chapter together with a few recommendations for future study. Dissert. Abstr.

Rapidly changing world events, the increased number of nations with inter-continental ballistic missile capability, and the proliferation of nuclear weapon technology will increase the number of nuclear threats facing the world today. Monitoring these nation's activities and providing an early warning and/or intercept system via reconnaissance and surveillance satellites and space based weapon platforms is a viable deterrent against a surprise nuclear attack. However, the deployment of satellite and weapon platform assets in space will subject the sensitive electronic equipment to a variety of natural and man-made radiation environments. These include Van Allen Belt protons and electrons; galactic and solar flare protons; and neutrons, gamma rays, and x-rays from intentionally detonated fission and fusion weapons. In this paper, the MASH vl.0 code system is used to estimate the dose to the critical electronics components of an idealized space based weapon platform from neutron and gamma-ray radiation emitted from a thermonuclear weapon detonation in space. Fluence and dose assessments were performed for the platform fully loaded, and in several stages representing limited engagement scenarios. The results indicate vulnerabilities to the Command, Control, and Communication bay instruments from radiation damage for a nuclear weapon detonation for certain source/platform orientations. The distance at which damage occurs will depend on the weapon yield (n,(gamma)/kiloton) and size (kilotons). DOE

The authors report the recovery of the ALEXIS small satellite mission. ALEXIS is a 113-kg satellite that carries an ultrasoft x-ray telescope array and a high-speed VHF receiver/digitizer (BLACKBEARD), supported by a miniature spacecraft bus. It was launched by a Pegasus booster on 1993 April 25, but a solar paddle was damaged during powered flight. Initial attempts to contact ALEXIS were unsuccessful. The satellite finally responded in June, and was soon brought under control. Because the magnetometer had failed, the rescue required the development of new attitude control-techniques. The telemetry system has performed nominally. They discuss the procedures used to recover the ALEXIS mission. DOE

During the last phase of the project, emphasis has changed to flexible space robotics, by mutual agreement between Dr. R. C. Montgomery, NASA Technical Officer, and the Principal Investigator. Significant advances have been achieved over the period covered by this report. Research has been concerned with two main subjects: (1) the maneuvering and control of freely floating flexible space robots, and (2) the development of a theory for the motion of flexible multibody systems. Work on the first subject has resulted in two papers, both of them concerned with planar maneuvers. The first is concerned with the maneuvering and delivery of a payload to a certain point and in a certain orientation in space. The second is concerned with the docking maneuver with a target whose motion is not known a priori. Both papers will appear in the 'Journal of Guidance, Control, and Dynamics.' The second subject is concerned with the development of hybrid (ordinary and partial) differential equations for the three dimensional motion of flexible multibody systems, a subject of vital interest in flexible space robotics. The paper will appear in the 'Journal of Guidance, Control and Dynamics' in an issue dedicated to the memory of Lawrence W. Taylor, Jr. Abstracts and copies of the papers are hereby included. Author

SPACECRAFT ENVIRONMENTAL ANOMALIES EXPERT SYSTEM
Harry C. Koons and David J. Groney 23 Feb. 1994 107 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-93-C-0094)
(AD-A277962; TR-93(3940)-11; SMC-TR-94-07) Avail: CASI HC A06

An expert system has been developed by The Aerospace Corporation, Space and Environment Technology Center for use in the diagnosis of satellite anomalies caused by the space environment. The expert system is designed to determine the probable cause of an anomaly from the following candidates: surface charging, bulk charging, single-event effects, total radiation dose, and space-plasma effects. Such anomalies depend on the orbit of the satellite, the local plasma and radiation environment (which is highly variable), the satellite-exposure time, and the hardness of the circuits and components in the satellite. The expert system is a rule-based system that uses the Texas Instrument's Personal Consultant Plus expert-system shell. The expert system's knowledgebase includes about 200 rules, as well as a number of databases that contain information on spacecraft and their orbits, previous spacecraft anomalies, and the environment. The Orbital Acceleration Research Experiment (OARE), which has flown on STS-40, STS-50, and STS-58, contains a three axis accelerometer with a single, nonpendulous, electrostatically suspended proofmass which can resolve accelerations to the nano-g level. The experiment also contains a full calibration station to permit in situ bias and scale factor calibration. This on-orbit calibration capability eliminates the large uncertainty of ground-based calibrations encountered with accelerometers flown in the past on the orbiter, thus providing absolute acceleration measurement accuracy heretofore unachievable. This is the first time accelerometer scale factor measurements have been performed on orbit. A detailed analysis of the calibration process is given along with results of the calibration factors from the on-orbit OARE flight measurements on STS-58. In addition, the analysis of OARE flight maneuver data used to validate the scale factor measurements in the sensor's most sensitive range is also presented. Estimates on calibration uncertainties are discussed. This provides bounds on the STS-58 absolute acceleration measurements for future applications. Author (revised)

The EOS Moderate Resolution Imaging Spectrometer (MODIS) is being developed by NASA for flight on the Earth Observing System (EOS) series of satellites, the first of which (EOS-AM-1) is scheduled for launch in 1998. This document describes the algorithms and their theoretical basis for the MODIS Level 1B characterization, calibration, and geolocation algorithms which must produce radiometrically, spectrally, and spatially calibrated data with sufficient accuracy so that Global change research programs can detect minute changes in biogeophysical parameters. The document first describes the geolocation algorithm which determines geodetic latitude, longitude, and elevation of each MODIS pixel and the determination of geometric parameters for each observation (satellite zenith angle, satellite azimuth, range to the satellite, solar zenith angle, and solar azimuth). Next, the utilization of the MODIS onboard calibration sources, which consist of the Spectroradiometric Calibration Assembly (SRCA), Solar Diffuser (SD), Solar Diffuser Stability Monitor (SDSM), and the Blackbody (BB), is treated. Characterization of these sources and integration of measurements into the calibration process is described. Finally, the use of external sources, including the Moon, instrumented sites on the Earth (called vicarious calibration), and unsupervised normalization sites having invariant reflectance and emissive properties is treated. Finally, algorithms for generating utility masks needed for scene-based calibration are discussed. Eight appendices are provided, covering instrument design and additional algorithm details. Author

Space nuclear power and nuclear electric propulsion are considered important technologies for planetary exploration, as well as selected earth

orbit applications. The Nuclear Electric Propulsion Space Test Program (NEPSTP) could provide an early flight demonstration of these technologies at relatively low cost through extensive use of existing Russian technology. The key element of Russian technology employed in the program is the Topaz II reactor. This space nuclear power system was built and flight qualified, though never tested in space, by the former Soviet Union. The NEPSTP is faced with many unique flight qualification issues. In general, the launch of a spacecraft employing a nuclear reactor power system will complicate many spacecraft qualification activities. However, the NEPSTP activities are further complicated because the reactor power system is a Russian design. Therefore, this program must deal not only with the unique flight qualification issues associated with space nuclear power, but also with differences between Russian and United States flight qualification procedures. This paper presents an overview of the NEPSTP. The program goals, the proposed mission, the spacecraft, and the Topaz II space nuclear power system are described. The subject of flight qualification is then examined. The inherent difficulties in qualifying a space reactor are described. The differences between United States and Russian flight qualification procedures are explored. A plan is then described to determine an appropriate flight qualification program for the Topaz II reactor to support a possible NEPSTP launch. DOE

(ISSN 0078-3781)
(ONERA-NT-1993-15; ETN-94-96067) Avail: CASI HC A12/MF A03

The internal aerodynamics of a solid propellant rocket motor is studied. Cold gas simulation setups are reviewed. The analysis of numerical approximations used for modeling such setups has led to the adoption of a k-L type description of turbulence. The numerical simulations of two cold flow setups enable the computer code to be checked in purely aerodynamic terms. The experimental subscale setup which allowed the construction of a database regarding the quasi steady heat exchanges generated on an inert wall within the combustion chamber of a rocket motor is described. The computations show that an approximation which does not require the use of a very fine grid at the wall is sufficient to reproduce the measured flux levels. A law of the wall is proposed which takes account of the effect of the steep temperature gradients and allows a better description of the measurements made. The evaluation of the ablation of a thermal insulation material placed in the combustion chamber of the test rocket motor is described. Teflon was employed in view of the simplicity of its degradation mechanisms. In terms of measurements, the difficulties inherent in the use of an ultrasonic method are shown. The dimensional measurements made constitute reference data through which it will be possible to check future computer codes for the ablation of thermal insulation. The validity of coupling an aerothermodynamic computer code and a module for evaluating the response of an insulation material is discussed. A full temporal numerical simulation of the tests is presented. ESA

This document summarizes the preliminary design of the Aerojet version of the Orbit Transfer Vehicle main engine. The concept of a 7500 lbf thrust LO2/GH2 engine using the dual expander cycle for optimum efficiency is validated through power balance and thermal calculations. The engine is capable of 10:1 throttling from a nominal 2000 psia to a 200 psia chamber pressure. Reservations are detailed on the feasibility of a tank head start, but the design incorporates low speed turbopumps to mitigate the problem. The mechanically separate high speed turbopumps use hydrostatic bearings to meet engine life requirements, and operate at sub-critical speed for better throttling ability. All components were successfully packaged in the restricted envelope set by the clearances for the extendible/retractable nozzle. Gimbal design uses an innovative primary and engine out gimbal system to meet the +/- 20 deg gimbal requirement. The hydrogen regenerator and LOX/GH2 heat exchanger uses the Aerojet platelet structures approach for a highly compact component design. The extendible/retractable nozzle assembly uses an electric motor driven jack-screw design and a one segment carbon-carbon or silicide coated columbium nozzle with an area ratio, when extended, of 1430:1. A reliability analysis and risk assessment concludes the report. Author

PERFORMANCE EVALUATION AND OPERATING CHARACTERISTICS OF A WAVEGUIDE MICROWAVE APPLICATOR FOR SPACE PROPULSION APPLICATIONS Ph.D. Thesis
Juergen Mueller 1993 311 p
Avail: Univ. Microfilms Order No. DA9326908

A new electrothermal space propulsion concept using waveguide heated plasmas was investigated. Attention was focused on the understanding of basic operational characteristics of this thruster concept. To this end, experimental testing of various waveguide applicator configurations was conducted. Waveguide-heated plasmas are not stable but tend to propagate toward the microwave power source due to heat conduction or radiative processes. A rectangular waveguide applicator was used to measure plasma propagation velocities. Plasma velocities in nitrogen were found to be around 10 cm/s. In helium two propagation modes were observed, one ranging in plasma velocities between 10 and 90 cm/s while the faster mode showed propagation velocities up to 2000 to 3000 cm/s. Inserting a bluff body made from boron nitride material into the gas flow enabled stabilization of the microwave discharge over given power ranges depending on mass flow rates and gas pressure. For the stabilized plasma in the rectangular guide up to 90 percent coupling efficiency, i.e. absorbed over total incident microwave power, were measured. However, it was observed that a rectangular waveguide plasma sustained in a TE(sub 10) electromagnetic field pattern touches the waveguide walls at two locations, possibly resulting in problems of thruster erosion and efficiency loss. Therefore a circular TM(sub 01) mode applicator was investigated. The microwave discharge in this applicator could be sustained well separated from the waveguide walls at coupling efficiencies up to 96 percent. For a simple converging conical nozzle arrangement, using measured data on power, pressure and mass flow rate and quasi-one dimensional nozzle flow theory, values for such rocket performance parameters as thruster efficiency, specific impulse and thrust were estimated to be 40 percent, 350 sec and 0.4 N, respectively. COMBUSTOR AND NOZZLE EFFECTS ON PARTICULATE BEHAVIOR IN SOLID ROCKET MOTORS M.S. Thesis
Bulent Yakin Dec. 1993 61 p
(AD-A277304) Avail: CASI HC A04/MF A01

An investigation was conducted using a subscale solid rocket motor to measure the effect of nozzle residence time on the behavior of Al2O3 particles to assess the applicability of subscale motor data to full-scale motors and to measure the effects of nozzle entrance particle size distribution on the slag accumulated with submerged nozzles. Although particles as large as 140 micrometers were present at the nozzle entrance, most of the particulate mass was contained in much smaller particles. This observation is in good agreement with the small mass that accumulated above the submerged nozzle. It was found that both particle breakup and collision coalescence occurred across the exhaust nozzle, with a significant

increase in the mass fraction of small (less than 2 micrometers) particles. Increasing the nozzle residence time enhanced particle breakup but did not affect the maximum plume particle size. Thus, full-scale motors are expected to have a higher percentage of mass in particles less than 2 micrometers than subscale motors but with similar diameters of the largest particles. DTIC

SUMMARY OF PARTICLE BED REACTOR DESIGNS FOR THE SPACE NUCLEAR THERMAL PROPULSION PROGRAM
J. R. Powell, H. Ludewig, and M. Todosow et al Sep. 1993 185 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-76CH-00016)
(DE94-007434; BNL-52408) Avail: CASI HC A09 (US Sales Only)

A summary report of the Particle Bed Reactor (PBR) designs considered for the space nuclear thermal propulsion program has been prepared. The first chapters outline the methods of analysis, and their validation. Monte Carlo methods are used for the physics analysis, several new algorithms are used for the fluid dynamics heat transfer and engine system analysis, and commercially available codes are used for the stress analysis. A critical experiment, prototypic of the PBR was used for the physics validation, and blowdown experiments using fuel beds of prototypic dimensions were used to validate the power extraction capabilities from particle beds. In all four different PBR rocket reactor designs were studied to varying degrees of detail. They varied in power from 400 MW to 2000 MW. These designs were all characterized by a negative prompt coefficient, due to Doppler feedback, and the feedback due to moderator heat up varied from slightly negative to slightly positive. In all practical cases, the coolant worth was positive, although core configurations with negative coolant worth could be designed. In all practical cases the thrust/weight ratio was greater than 20. THE EFFECT OF DUCTILE PHASE (Nb) REINFORCEMENT MORPHOLOGY ON THE MECHANICAL BEHAVIOR OF AN INTERMETALLIC MATRIX (MoSi2) Ph.D. Thesis
David E. Alman 1992 190 p
Avail: Univ. Microfilms Order No. DA9314339

This thesis was undertaken to determine the effect of a ductile reinforcement phase (Nb) morphology on the mechanical behavior of an intermetallic matrix (MoSi2). Twenty volume percent Nb was incorporated into MoSi2 in the form of particles, short fibers, aligned fibers, and with fibers of two different diameters (800 and 400 microns). Bend tests, comprehension tests and fractography were used to determine the role that Nb morphology plays on the fracture behavior of these composites. It was found that the morphology of the Nb incorporated into MoSi2 affected the fracture mechanism, hence toughness, of the composites. The addition of random short fiber or particles deflected cracks that propagated through the matrix. However, the Nb in these forms were not effective in improving the toughness via a crack deflection mechanism. The addition of continuous Nb fibers aligned perpendicular to the direction of crack propagation enhanced the toughness of MoSi2, as these fibers deformed and fractured prior to composite failure, however, there was an effect of fiber diameter. The larger diameter Nb fibers imparted the greatest toughness improvements, as these fibers deformed prior to fracture. The smaller diameter Nb did not deform prior to fracture, in fact they failed in a brittle manner. Fractography revealed that the larger diameter fibers had separated (or delaminated) from the matrix. The fiber/matrix separation relaxed the matrix constraint acting on the fiber and allowed for the fiber to undergo plastic deformation. The delamination was found to occur after the matrix had fractured and prior to deformation of the fibers. This would indicate that the delamination occurs by a pull-out mechanism. The diameter effect exhibited by the composites was attributed to the well known effect of fiber aspect ratio (l/d) on fiber pull-out. It was concluded that maximum toughness of a Nb fiber reinforced MoSi2 matrix will occur when the value of the fiber aspect ratio is within a critical range. The upper limit must not be exceeded to ensure fiber pull-out will occur; and the lower limit must be exceeded to ensure that matrix cracks do not deflect around the fiber. Dissert. Abstr.

The Nuclear Electric Propulsion Space Test Program (NEPSTP) is sponsored by the Ballistic Missile Defense Office (BMDO) to demonstrate and evaluate the Russian-built TOPAZ 2 nuclear reactor as a power source for an electric propulsion system in space. From its inception, safety has been a central feature of the NEPSTP program. This paper addresses the work done to define the safety organizational relationships, responsibilities, management, engineering requirements, and documentation to assure an integrated safety program that coordinates the various safety activities in Mission Safety, Range Safety and Nuclear Safety. Because the United States has not launched a nuclear reactor since 1965, much of the focus of the safety program has been directed toward the unique safety considerations of using a nuclear reactor in space. Our preliminary findings indicate that the safe use of the TOPAZ 2 for the NEPSTP space mission is feasible. DOE

Avail: CASI HC A02/MF A01

The direct simulation Monte-Carlo (DSMC) method was applied to the analysis of low-density nitrogen plumes exhausting from a small converging-diverging nozzle into finite ambient pressures. Two cases were considered that simulated actual test conditions in a vacuum facility. The numerical simulations readily captured the complicated flow structure of the overexpanded plumes adjusting to the finite ambient pressures, including Mach disks and barrel shaped shocks. The numerical simulations compared well to experimental data of Rothe. Author

(NASA-CR-185297; NAS 1.26:185297) Avail: CASI HC A05/MF A01

Test results of oscillating flow losses in rectangular heat exchanger passages of various aspect ratios are given. This work was performed in support of the design of a free-piston Stirling engine (FPSE) for a dynamic space power conversion system. Oscillating flow loss testing was performed using an oscillating flow rig, which was based on a variable stroke and variable frequency linear drive motor. Tests were run over a range of oscillating flow parameters encompassing the flow regimes of the proposed

engine design. Test results are presented in both tabular and graphical form and are compared against analytical predictions. Author

(NASA-CR-182149; NAS 1.26:182149) Avail: CASI HC A03/MF A01

As part of the NASA CSTI High Capacity Power Program on Conversion Systems for Nuclear Applications, Sunpower, Inc. completed for NASA Lewis a reference design of a single-cylinder free-piston Stirling engine that is optimized for the lifetimes and temperatures appropriate for space applications. The NASA effort is part of the overall SP-100 program which is a combined DOD/DOE/NASA project to develop nuclear power for space. Stirling engines have been identified as a growth option for SP-100 offering increased power output and lower system mass and radiator area. Superalloy materials are used in the 1050 K hot end of the engine; the engine temperature ratio is 2.0. The engine design features simplified heat exchangers with heat input by sodium heat pipes, hydrodynamic gas bearings, a permanent magnet linear alternator, and a dynamic balance system. The design shows an efficiency (including the alternator) of 29 percent and a specific mass of 5.7 kg/kW. This design also represents a significant step toward the 1300 K refractory Stirling engine which is another growth option of SP-100. Author

The Los Alamos National Laboratory Coaxial Thruster Experiment (CTX) has been upgraded to enable the quasisteady operation of magnetoplasmadynamic (MPD) type thrusters at power levels from 2 to 40 MW for 10 ms. Diagnostics include an eight position, three axis magnetic field probe to measure magnetic field fluctuations during the pulse; a triple Langmuir probe to measure ion density, electron temperature, and plasma potential; and a time-of-flight neutral particle spectrometer to measure specific impulse. Here we report on the experimental observations and associated analysis and interpretation of long-pulse, quasisteady, coaxial thruster performance in the CTX device. Author

EXPOSURE ASSESSMENT OF JAVELIN MISSILE COMBUSTION PRODUCTS Technical Report, 1987 - 1992
Donald O. Lundy and Roland E. Langford 14 Feb. 1994 63 p
(AD-A278128; TR-94-0002) Avail: CASI HC A04/MF A01

Characterization and analysis of combustion products resulting from firing the JAVELIN missile were performed. Of those combustion products analyzed, it was determined that airborne lead concentrations exceeded the OSHA PEL of 50 micrograms each time the missile was fired while in the enclosure. Since the OSHA PEL standard is based upon a continuous rather than a short-term exposures blood lead concentrations were sought to ascertain the relationship between a short duration airborne exposure and its physiological effect on the body. Blood lead levels were taken on 49 test subjects prior to various JAVELIN missile test firings. Of those 49, 21 were outfitted With personal sampling equipment to determine airborne concentrations at the Assistant Gunner and Gunner positions. Periodic blood sampling after a single exposure showed an average increase of 2.27 micrograms/dL for all test subjects. Recommendations were made to consider changes in the positioning of the enclosure inhabitants to minimize airborne lead concentrations, to limit the number of missiles fired (situation dependent), and replacement of the lead B-resorcyolate with a non-lead containing burn rate modifier for the launch motor. POSSIBLE EFFECT OF THE CHLORINE OXIDE DIMER ON TRANSIENT OZONE LOSS IN ROCKET PLUMES
L. R. Martin 15 Mar. 1994 16 p
(Contract F04701-93-C-0094)
(AD-A278135; TR-94(4231)-1; SMC-TR-94-14) Avail: CASI HC A03/MF A01

Understanding transient, local ozone holes that may be produced by solid rocket boosters in the stratosphere puts special demands on models. One must consider the time scales as well as the rates for all of the pertinent chemical reactions involved in the destruction of ozone. In this report, we show that consideration of the existence of the chlorine oxide dimer, Cl2O2, and consideration of the necessary time scale for ozone loss are essential for prediction of a transient ozone hole. We argue that photolysis of this species is the major source of atomic chlorine in the plume at 20 km, and the ClO + O reaction is the major source at 30 km, although both processes play a role at the higher altitude. Inclusion of the chlorine oxide dimer ozone destruction cycle, which has not been considered in any of the full-scale models to date, predicts substantial ozone destruction on a scale of about 12-km diameter at 20-km altitude and the ClO cycle produces a 49-km-diameter hole at 30-km altitude. This analysis also suggests that the size of the hole at 20 km may be highly variable since it is sensitive to the variable ozone-to-methane ratio at that altitude. DTIC

REAL-TIME SENSOR DATA VALIDATION Final Report
Timothy W. Bickmore Apr. 1994 74 p
(Contract NAS3-25883; RTOP 584-03-11)
(NASA-CR-195295; E-8672; NAS 1.26:195295) Avail: CASI HC A04/MF A01

This report describes the status of an on-going effort to develop software capable of detecting sensor failures on rocket engines in real time. This software could be used in a rocket engine controller to prevent the erroneous shutdown of an engine due to sensor failures which would otherwise be interpreted as engine failures by the control software. The approach taken combines analytical redundancy with Bayesian belief networks to provide a solution which has well defined real-time characteristics and well-defined error rates. Analytical redundancy is a technique in which a sensor's value is predicted by using values from other sensors and known or empirically derived mathematical relations. A set of sensors and a set of relations among them form a network of cross-checks which can be used to periodically validate all of the sensors in the network. Bayesian belief networks provide a method of determining if each of the sensors in the network is valid, given the results of the cross-checks. This approach has been successfully demonstrated on the Technology Test Bed Engine at the NASA Marshall Space Flight Center. Current efforts are focused on extending the system to provide a validation capability for 100 sensors on the Space Shuttle Main Engine. Author

This contract supported the development of the technology of trapping of organic molecules and enzymes in porous sol-gel matrices. Our work led to the preparation and design of a wide range of novel optical materials. We summarize past achievements and recent progress made in the development of several classes of these materials representing the diversity that the trapping approach allows: chemical sensors, enzymatic sensors, electrooptical liquid crystal materials, luminescent materials, and photochromic materials. Emphasis in this Report is given to our own results, and in addition, results from other laboratories, which are based on our developments and which are of high relevance to the topic of the Project (e.g., liquid crystal sol-gel displays), are summarized as well. We regard these other technological fruits a direct outcome of our sol-gel research. DTIC

THE EFFECT OF PROLONGED EXPOSURE TO 750 C AIR ON THE TRIBOLOGICAL PERFORMANCE OF PM212
Kirk Bernis (Case Western Reserve Univ., Cleveland, OH.), Michael S. Bogdanski (Case Western Reserve Univ., Cleveland, OH.), Christopher DellaCorte, and Harold E. Sliney Feb. 1994 27 p Presented at the STLE Annual Meeting, Pittsburgh, PA, 2-5 May 1994; sponsored by the Society of Tribologists and Lubrication Engineers
(Contract DE-A101-91CE-50306)
(NASA-TM-106472; E-8341; NAS 1.15:106472; DOE/NASA/50306-4)
Avail: CASI HC A03/MF A01

The effect of prolonged exposure to 750 C air on the tribological performance and dimensional stability of PM212, a high temperature, self-lubricating composite, is studied. PM212, by weight, contains 70 percent metal-bonded Cr3C2, 15 percent BaF2/CaF2 eutectic, and 15 percent silver. Rub blocks were fabricated from PM212 by cold isostatic pressing followed by sintering. Prior to tribo-testing, the rub blocks were exposed to 750 C air for periods ranging from 100 to 1000 hours. Then, the rub blocks were slid against nickel-based superalloy disks in a double-rub-block tribometer in air under a 66 N load at temperatures from 25 to 750 C with a sliding velocity of 0.36 m/s. Unexposed rub blocks were tested for baseline comparison. Friction coefficients ranged from 0.24 to 0.37 for the unexposed rub blocks and from 0.32 to 0.56 for the exposed ones. Wear for both the composite blocks and superalloy disks was typically in the moderate to low range of 10(exp -5) to 10(exp -6) mm(exp 3)/N-m. Friction and wear data were similar for the rub blocks exposed for 100, 500, and 1000 hours. Prolonged exposure to 750 C air increased friction and wear of the PM212 rub blocks at room temperature, but their triboperformance remained unaffected at higher temperatures, probably due to the formation of lubricious metal oxides. Dimensional stability of the composite was studied by exposing specimens of varying thicknesses for 500 hours in air at 750 C. Block thicknesses were found to increase with increased exposure time until steady state was reached after 100 hours of exposure, probably due to oxidation. Author (revised)

(NASA-TM-106547; E-8697; NAS 1.15:106547) Avail: CASI HC A04/MF A01

The decomposition of Fomblin Z25, a commercial perfluoropolyalkylether liquid lubricant, was studied using the Penn State Micro-oxidation Test, and a thermal gravimetric/differential scanning calorimetry unit. The micro-oxidation test was conducted using 440C stainless steel and pure iron metal catalyst specimens, whereas the thermal gravimetric/differential scanning calorimetry tests were conducted using catalytic alumina pellets. Analysis of the thermal data, high pressure liquid chromatography data, and x-ray photoelectron spectroscopy data support evidence that there are two different decomposition mechanisms for Fomblin Z25, and that reductive sites on the catalytic surfaces are responsible for the decomposition of Fomblin Z25. For spacecraft in low Earth orbit (LEO), contamination can occur from thruster fuel, sputter contamination products and from products of silicone degradation. This paper describes laboratory testing in which solar cell materials and thermal control surfaces were exposed to simulated spacecraft environmental effects including contamination, atomic oxygen, ultraviolet radiation and thermal cycling. The objective of these experiments was to determine how the interaction of the natural LEO environmental effects with contaminated spacecraft surfaces impacts the performance of these materials. Optical properties of samples were measured and solar cell performance data was obtained. In general, exposure to contamination by thruster fuel resulted in degradation of solar absorptance for fused silica and various thermal control surfaces and degradation of solar cell performance. Fused silica samples which were subsequently exposed to an atomic oxygen/vacuum ultraviolet radiation environment showed reversal of this degradation. These results imply that solar cells and thermal control surfaces which are susceptible to thruster fuel contamination and which also receive atomic oxygen exposure may not undergo significant performance degradation. Materials which were exposed to only vacuum ultraviolet radiation subsequent to contamination showed slight additional degradation in solar absorptance. Author

DEVELOPMENT OF LIGHTWEIGHT CERAMIC ABLATORS AND ARC-JET TEST RESULTS
Huy K. Tran Jan. 1994 27 p
(RTOP 506-46-31)
(NASA-TM-108798; A-94017; NAS 1.15:108798) Avail: CASI HC A03/MF A01

Lightweight ceramic ablators (LCA's) were recently developed at Ames to investigate the use of low density fibrous substrates and organic resins as high temperature, high strength ablative heat shields. Unlike the traditional ablators, LCA's use porous ceramic/carbon fiber matrices as substrates for structural support, and polymeric resins as fillers. Several substrates and resins were selected for the initial studies, and the best performing candidates were further characterized. Three arcjet tests were conducted to determine the LCA's thermal performance and ablation characteristics in a high enthalpy, hypersonic flow environment. Mass loss and recession measurements were obtained for each sample at post test, and the recession rates were determined from high speed motion films. Surface temperatures were also obtained from optical pyrometers. Author

AN EFFICIENT HIGHER ORDER THEORY FOR LAMINATED COMPOSITE PLATES AND A FINITE ELEMENT IMPLEMENTATION
Ph.D. Thesis
Maeng-Hyo Cho 1993 209 p
Avail: Univ. Microfilms Order No. DA9326349

An efficient higher order plate theory for laminated composites is developed. A composite plate theory for symmetric and general lamination configurations is obtained by superposing a cubic varying displacement field on a piecewise linearly varying displacement. The theory has the same number of dependent unknowns as first-order shear deformation theory, and the number of unknowns is independent of the number of

layers. The displacement satisfies transverse shear stress continuity conditions at the interface between layers as well as shear free surface conditions. Thus an artificial shear correction factor is not needed. To demonstrate and compare with other theories, the analytical solution for cylindrical bending is obtained. To solve problems of more general engineering interest, a triangular finite element based on an efficient higher order plate theory (EHOPT) is developed for symmetric laminated composites. The nonconforming element has 5 degrees of freedom in each node. It passes proper bending and shear patch tests in arbitrary meshes in isotropic materials. Thus it converges to the exact solution. To demonstrate and compare with other theories, the finite element solutions for a static bending problem under sinusoidal loading is obtained. The present finite element result gives deflections and stresses which agree very well with 3 dimensional elasticity solutions. However, it suffers from transverse shear locking in thin plates. For the complete elimination of the locking behavior, a modified formulation of the EHOPT (MEHOPT) is proposed. These EHOPT and MEHOPT elements provide an efficient and accurate tool for the analysis of thick multilayered composite plates.

A micromechanical study of the interface in glass fiber/epoxy matrix model composites was carried out using pull out, fragmentation and microindentation tests. Focus was on the two first tests due to the particular case of glass/epoxy systems of microindentation. The influence of the fiber silane size on the load transfer and on the damage elementary modes was studied. The experimental fragmentation processes were compared with those obtained from an analytical simulation of the fragmentation test and it was proved that one dimensional load transfer models did not allow a satisfactory description of the fragmentation process in glass/epoxy systems. Bidimensional models are more suitable for the analysis of the experimental data because they give an account of the multiaxial aspect of the fiber/matrix load transfer. However, some experimental phenomenon such as debonding interfacial plasticization and fiber/matrix friction are difficult to take into account in such bidimensional models. Moreover, a thorough examination of load transfer models recently developed for the pull out test showed that they cannot lead to a precise mechanical analysis and that a bidimensional load transfer should be envisaged. Accordingly, the mechanical analysis of these micromechanical tests has to be improved in order to take into account more precisely the local stress concentrations in the fiber/matrix system and the real mechanical behavior of the matrix. A study to better understand compressive behavior of composites is reported. The comparison of composite compression test methods and the development of a micromechanical test on a single filament specimen to characterize the carbon fiber compressive behavior are presented. The macroscopic approach points out the major effect of structural parameters when compared to materials characteristics. It appears indeed that the composite failure in compression depends strongly on the loading mode (axial compression or bending) as well as on the type of lay up. Micromechanical tests were interpreted with the help of an analytical model of fiber microbuckling. The results emphasize the high strain capability of the carbon fiber in compression. Accordingly, the compressive failure of composites is due to a combined fibers/matrix effect: the fiber cooperative microbuckling and the weaker antibuckling support of the matrix in the composite lead to a premature failure when compared to the single filament specimen case. This project has initiated and brought to completion several novel microscopic approaches to the prediction of material response to applied stress. In a series of several papers we worked out a systematic formulation of failure under load as a homogeneous nucleation process, simulating the process via mean-field, Monte Carlo and molecular dynamics methods, for both model and semi-empirical interatomic potentials. We also developed a biased-random-walk description of microcrack propagation which incorporated for the first time the effects of surface reconstruction. Finally we extended multiple scattering analyses of composite and concrete materials to the limit of high crack density, allowing for new nondestructive evaluations of this important class of materials. INELASTIC DEFORMATION OF METAL MATRIX COMPOSITES Ph.D. Thesis
Clifford Jesse Lissenden 1993 209 p
Avail: Univ. Microfilms Order No. DA9327902

A theoretical model capable of predicting the thermomechanical response of continuously reinforced metal matrix composite laminates subjected to multiaxial loading has been developed. A micromechanical model is used in conjunction with nonlinear lamination theory to determine inelastic laminate response. Matrix viscoplasticity, residual stresses, and damage to the fiber/matrix interfacial zone are explicitly included in the model. The representative cell of the micromechanical model is considered to be in a state of generalized plane strain, enabling a quasi two dimensional analysis to be performed. Constant strain finite elements are formulated with elastic-viscoplastic constitutive equations. Interfacial debonding is incorporated into the model. Nonlinear interfacial constitutive equations relate interfacial tractions to displacement discontinuities at the interface. Theoretical predictions are compared with the results of an experimental program conducted on silicon carbide/titanium (SiC/Ti) unidirectional, (O(sub 4)), and angle-ply, (+/- 45)(sub s), tubular specimens. Multiaxial loading included increments of axial tension, compression, torque, and internal pressure. Loadings were chosen in an effort to distinguish inelastic deformation due to damage from matrix plasticity and separate time-dependent effects from time-independent effects. Results show that fiber/matrix debonding is nonuniform throughout the composite and is a major factor in the effective response. Also, significant creep behavior occurs at relatively low applied stress levels at room temperature.

EFFECTS OF OXIDATION AND CREEP DAMAGE MECHANISMS ON CREEP BEHAVIOR IN HIPed SILICON NITRIDES
A. A. Wereszczak, M. K. Ferber, and T. P. Kirkland 1994 8 p Presented at the 18th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 9-14 Jan. 1994
(Contract DE-AC05-84OR-21400)
(DE94-006559; CONF-940135-3) Avail: CASI HC A02/MF A01

The creep resistance of hot-isostatically pressed (HIPed) silicon nitride materials is ultimately dictated by its susceptibility to creep enhanced damage (e.g. cavitation) and oxidation induced damage. The evolution of these simultaneously occurring events has been examined in several HIPed silicon nitrides which were tested in tension at elevated temperatures. The activity and extent of each have found to be functions of several variables. These

parameters and their roles are discussed and include the following: initial alpha/beta ratio of silicon nitride grains, reaction of stable/unstable phases in the as-received material, percentage and type of sintering aid, and grain boundary crystallinity, impurity content, and viscosity. DOE

The resolution of three problems related to the principle of atmospheric plasma spraying usually used for realizing thermal barriers consisting of a zirconium layer sprayed on metallic substrate is reported. The problems concern: substrate corrosion through deposit porosities; residual constraints due to differences of the metal and ceramic thermal dilation coefficients; lack of adherence between the metal and the ceramic. These problems were resolved by the development of aluminide intermediary layers realized by interdiffusion of aluminum with the metallic substrate (steel or cast). Optimization of these layers was done by the use of thermomechanical characterizations (traction, thermal fatigue) associated to controls by ultrasonic mapping. The particularly favorable role of additions of silicon and above all yttrium and existence of an optimal torch/piece relative speed are shown. The results obtained are better than those given by classical solutions. ESA

STUDY OF WAVE PROPAGATION AND DYNAMIC RESPONSE OF LAMINATED COMPOSITE STRUCTURES Final Report, Jun. 1990 - Nov. 1993
Rakesh K. Kapania and J. N. Reddy 24 Jan. 1994 17 p
(Contract DAAL03-90-G-0134)
(AD-A276123; ARO-26908.14-EG) Avail: CASI HC A03/MF A01

We conducted a fundamental study to investigate the dynamic behavior of laminated structures. Both finite element and analytical solutions were developed. Using a 48 degree of freedom shell finite element (FE) developed by Kapania and coworkers, the effect of arbitrary inplane and out-of-plane loads on the transverse vibrations of thin arbitrarily laminated panels with or without geometric imperfections was analyzed. The element was used to investigate the effect of geometric imperfections on geometrically nonlinear impact response of thin laminated plates and cylindrical panels using reduced basis methods. A FE model was also developed to study the linear and geometrically nonlinear transient behavior of laminated beams. A postprocessor was developed that can use the transverse displacements from a classical laminated plate theory (CLPT) or a first order shear deformation theory (FSDT) to determine the transverse normal and shear stresses. The nonlinear dynamic equations of the first-order shear deformation theory and the third-order shear deformation plate theory of Reddy was reformulated to describe the interior and edge zone problems of rectangular plates. A three dimensional elasticity solution for the free vibration analysis of general cross-ply laminated plates has been carried out by combining Fourier series solution with a state space representation and the transfer matrix approach. A close theoretical examination has clarified the accuracy of the various single layer theories and a layerwise theory with the exact elasticity solution. DTIC

A study whose aim is to evaluate the interface influence on carbon/bismaleimide composites properties for temperature as high as 250 C is reported. The interface is characterized at different temperatures by pull out test and at room temperature by fragmentation and impregnated tow tensile tests. For the pull out test, the interfacial shear strength variation with temperature comes from matrix properties evolution and residual thermal stresses modification as well. The residual stresses, evaluated by finite elements, are modified by temperature and the coefficient of thermal expansion of the specimen holder. For the fragmentation test, an attempt is made to obtain a good 'coaxial' specimen which can lead to a mechanical analysis and determination of the mean shear stress. In a fragmentation test simulation, the 'coaxial' geometry in the specimen stress calculation and the pull out test results for debonding stress choice are taken into account. For the impregnated tow tensile test, a statistical analysis of debonding length distribution from the fracture surface observation is made. With a model which gives the mean debonding length, a link is established between these results and the fragmentation results. This study is a step beyond the understanding of composite properties evolution with temperature. ESA

ON THE MECHANICS OF STRESS ANALYSIS OF FIBER-REINFORCED COMPOSITES Ph.D. Thesis
Ven-Gen Lee 1993 132 p
Avail: Univ. Microfilms Order No. DA9327240

A general mathematical formulation is developed for the three-dimensional inclusion and inhomogeneity problems, which are practically important in many engineering applications such as fiber pullout of reinforced composites, load transfer behavior in the stiffened structural components, and material defects and impurities existing in engineering materials. First, the displacement field (Green's function) for an elastic solid subjected to various distributions of ring loading is derived in closed form using the Papkovich-Neuber displacement potentials and the Hankel transforms. The Green's functions are used to derive the displacement and stress fields due to a finite cylindrical inclusion of prescribed dilatational eigenstrain such as thermal expansion caused by an internal heat source. Unlike an elliptical inclusion, the interior stress field in the cylindrical inclusion is not uniform. Next, the three-dimensional inhomogeneity problem of a cylindrical fiber embedded in an infinite matrix of different material properties is considered to study load transfer of a finite fiber to an elastic medium. By using the equivalent inclusion method, the fiber is modeled as an inclusion with distributed eigenstrains of unknown strength, and the inhomogeneity problem can be treated as an equivalent inclusion problem. The eigenstrains are determined to simulate the disturbance due to the existing fiber. The equivalency of elastic field between inhomogeneity and inclusion problems leads to a set of integral equations. To solve the integral equations, the inclusion domain is discretized into finite number of sub-inclusions with uniform eigenstrains, and the integral equations are reduced to a set of algebraic equations. The distributions of eigenstrains, interior stress field and axial force along the fiber are presented for various fiber lengths and the ratio of material properties of the fiber relative to the matrix. The approach is applied to two specific problems: the load transfer of a finite cylindrical fiber into a semi-infinite matrix and the fiber with protective coating embedded in an elastic half-space. Finally, the displacement field due to a stationary dislocation loop in an elastic half-space is obtained using the Green's functions derived previously. With constant discontinuity of displacement prescribed along the circumference of a cylindrical inclusion, the results can be used to model the interfacial sliding between fiber and matrix in fiber-reinforced composites. ON THE CONSTITUTIVE RESPONSE OF TRANSVERSELY LOADED FIBER COMPOSITES WITH COMPLIANT INTERPHASES Ph.D. Thesis
Michael Richard Gosz 1993 127 p
Avail: Univ. Microfilms Order No. DA9327199

The nature of fiber/matrix interphases in unidirectional fiber reinforced composites is known to significantly affect the overall behavior, especially the transverse behavior and the progressive failure under axial loading. However, there is still a lack of understanding of the local interphase behavior at the microscopic level and how this behavior influences the overall mechanical behavior and fracture at the macroscopic level. The present investigation addresses this issue from a mechanics perspective and attention is focused on the transverse behavior, where the loading is

applied perpendicular to the fiber direction. The phase geometry of the composite is modeled by a regular hexagonal array of circular fibers in a matrix. The interphase is described by a spring-layer model which permits jumps in displacement across a representative interface and assumes that the jumps are proportional to the conjugate tractions transmitted across that interface. Finite element calculations are carried out over a representative cell to obtain the mechanical response of the composite. The finite element method is then used an iterative mode to obtain the interphase properties given measured values of the composite's effective elastic constants. A modification to the spring-layer model which prevents a physically unrealistic radial overlap between the fiber and matrix phases has been recently proposed. A combined analytical and numerical method is developed to study the effect of the constraint on the response of the composite under general in-plane loading conditions. It is demonstrated that the transverse response is load-dependent and anisotropic under certain combinations of applied loading. The validity of the methodology and numerical results is established by invoking a new result in two-dimensional elasticity called the CLM theorem. In order to investigate the role of interphases in the transverse failure of fiber composites, a variationally coupled finite element - boundary element method is developed. After demonstrating the effectiveness of the method through examples in fracture mechanics and micromechanics, the method is employed to obtain the mechanical response, including the overall cracking patterns, of a hexagonal representative cell containing a center fiber and parts of surrounding fibers. It is shown that the interfacial stiffness and strength significantly affect the overall transverse stiffness and strength of the composite. Dissert. Abstr.

ULTRASONIC TOMOGRAPHY IN FIBER-REINFORCED COMPOSITE MATERIALS Ph.D. Thesis
Yuqin Wang 1993 169 p
Avail: Univ. Microfilms Order No. DA9322515

In this work two approaches to tomographic imaging in fiber composite materials are introduced. The objective is to image the inhomogeneities of matrix properties while the source of anisotropy is known (the reinforcing fibers for fiber composites). For one approach, which is based on a simple geometric ray analysis, the traditional ART (Algebraic Reconstruction Technique) reconstruction algorithm is modified so that it accommodates the directional dependence of material properties and beam skewing due to the reinforcing fibers. In order to improve the reconstruction accuracy, a ray tracing technique based on the variational formulation of Fermat's principle is incorporated in the modified ART. It has been found that good agreement can be achieved for both synthetic and experimental data when the straight-ray-path assumption is applied to specimens with small inhomogeneities. It is also found that the iterative ray tracing technique is capable of finding 'shorter time' ray paths in most cases and reducing errors in the reconstructed images especially when relatively large inhomogeneities exist and velocity (or material property) profiles are relatively simple. In the alternative approach based on the field theory of wave propagation, one numerically solves the governing equations for wave propagation using a finite difference method. A finite difference scheme valid for the general case of a heterogeneous, anisotropic medium is used. It is shown that by directly solving the wave equation with proper boundary conditions, one can solve both the direct problems and the inverse problems. In the direct problems, the material properties are assumed to be known and the task is to compute the field variables in wave propagation or to predict various wave phenomena such as reflection, refraction, etc. or to quantitatively estimate the time of propagation and other experimentally measurable quantities. In the inverse problem, the material properties are reconstructed from experimentally measured data. In solving the travel time tomography problem, an iterative algorithm similar to the traditional ART technique is developed. The iterative process is based on evaluation of the sensitivity factors by perturbing the material properties. Using this reconstruction approach, the ray tracing problem and energy deviation problem associated with the conventional imaging algorithms are automatically solved. In this project, the finite difference approach has been applied to both direct problems and inverse problems. Results for simulations of wave fields are obtained. Material properties have also been successfully reconstructed from the time delay data for both isotropic and anisotropic media. Dissert. Abstr.

The thesis presents a part of the work on powder metallurgical processing of Al-matrix composites, conducted in the frame of a research program of the Foundation for Fundamental Research of Matter with financial support from the Foundation for Technological Sciences. This thesis is based on a collection of papers and follows the chronology of powder metallurgy (P/M) processing steps up to the evaluation of the semifinished product. The knowledge gathered during the several processing stages of mixing, compaction, degassing, extrusion, and evaluation provides valuable insight in the nature of problems one may be confronted with in working these materials. Metal matrix composites reinforced with ceramics are of interest to the aerospace and auto industries. Studies have shown Al2O3 has promise as a component of those materials. The formation of Al2O4 in Al-Mg composites reinforced with Al2O3 was studied using electron energy loss spectroscopy. In studies conducted on composites processed in the liquid state, it is noted that nucleation at low temperature (700 C) is initially produced at secondary heterogeneous sites. At low and high (800 C) temperature, nucleation times correspond to formation of MgAl2O4 on the reinforcement surfaces which act as a substrate. A phenomenological model of MgAl2O4 growth is proposed in which the elements needed for forming MgAl2O4 from the liquid phase come from the Al-Mg alloy and from Al2O3 in an intermediate reaction. Experiments were conducted to identify the influence of the crystallography on the morphology of the MgAl2O4 phase, the reaction kinetics, and the nucleation and growth at 700 and 800 C. From the results, a model for the atomic structure configuration between the Al2O3 and MgAl2O4 lattices during the growth of (111) planes on alumina surfaces with (0001) orientation is proposed. The substrate orientation that retards MgAl2O4 formation is identified. The contribution of an anisotropic mechanical elastic energy was evaluated for a nucleus precipitated on a (0001) surface. The effects of processing conditions on the crystallization kinetics and fiber/matrix interactions in polyether ether ketone (PEEK)/carbon fiber composite were investigated. The molding cycle was simulated by differential scanning calorimetry. Simulation results show that increasing the cooling rate affects the crystallization parameters. Increasing the residence time at the molding temperature results in a significant decrease in the overall rate of crystallization. The activation energy related to the crystallization process depends on the cooling rate. A study of the PEEK crystalline structure shows that a rise in the cooling rate increases the number of nucleation sites and decreases the size of the crystalline entities; longer residence time at molding temperature increases the size of those entities. The interfacial strength in the composite, evaluated by a short beam shear test, was also significantly influenced by molding parameters. An increase in molding temperature and residence time at this temperature augments

the interfacial strength, while an increase in the cooling rate significantly reduces it. Improvement in fiber/matrix interaction occurs only for laminates in which strong fiber/matrix interaction is created during the molding process. The rupture mode is ductile before annealing, while it becomes fragile afterwards. Author (CISTI)

The interlaminar shear fatigue behavior of unidirectional pultruded half-round composite rods is examined. Four materials were subjected to three-point load-controlled bending tests under a triangular waveform loading signal. The fatigue test results show that the two glass fiber reinforced epoxy materials performed better than a polyester or a vinylester reinforced by glass fibers. For all tests undertaken, a transition from interlaminar shear failure to flexural failure was observed when the stress went from high values to low values. Between these limits, there is a mixed mode of fracture. This behavior is explained qualitatively based on geometric considerations. This was confirmed by additional tests using trapezoidal cross section beams and on a specimen subjected to a four point bending test where no shear/tension transition was noted from high to low stress fatigue. For a given stress amplitude, the failure mode can be predicted from the flexural bending tests with a large span to depth ratio. With that test, it is also possible to determine the stress amplitude corresponding to the transition point in the failure mode. The fatigue tests performed using different loading waveforms show that the lifetime decreases when passing from a triangular to a square waveform. Fatigue life is reduced by a factor of 1,000 when temperature is increased from 27 C to 100 C.

EVALUATING IN-PLANE ELASTIC CONSTANTS OF DAMAGED CARBON-EPOXY LAMINATES USING A QUANTITATIVE ULTRASONIC TECHNIQUE Ph.D. Thesis
Kenneth G. Kellogg 1992 174 p
Avail: Univ. Microfilms Order No. DA9316773

To fully utilize an engineering material, it is necessary to know and understand the total mechanical behavior of the material, both damaged and undamaged. This paper addresses the effect of impact damage on the tensile properties of a laminated carbon-epoxy angle-ply composite and its relationship to ultrasonic scanning data. Numerous coupons at various orientations were fabricated and impacted. These coupons were then ultrasonically scanned for damage assessment and comparisons were made. In addition, each coupon underwent a tensile failure test to determine the principal elastic constants and failure strengths. During the tensile tests, acoustic emission data were also collected to determine when load redistribution occurs. All of the collected data were then analyzed and discussed. From the collected data it was determined that ultrasonic wave speed measurements, in conjunction with Christoffel's equation, can be used to check the calculated extensional stiffnesses for laminated composites. In addition, the mechanical failure tests reveal that the use of classical lamination theory to determine the major and minor Young's moduli and Poisson's ratios of a laminate is very accurate provided good constituent property values are known initially. In terms of ultrasonic C-scans, it was concluded that through-the-thickness information can be obtained by utilizing a focussing transducer at oblique incidence. The wave forms obtained in this way must then be carefully scrutinized to determine what part of the waveform is essential. The comparison of damaged to undamaged strengths revealed that the tensile properties of the laminate were not noticeably affected at the impact energy levels used in this research. It was concluded that for tensile properties to be affected, considerable fiber damage must be present. Dissert. Abstr.

The final properties of metal matrix composites, if estimated by considering the properties of their components, do not conform to the composites' actual properties. This is attributed to reinforcement degradation and poor bonding between matrix and reinforcement. It is well-accepted that the key to maximizing interfacial bond strength is to promote wetting at the metal/ceramic interface. A study was conducted on ways of enhancing this wetting, on methods of quantifying wetting, and on the relation between interfacial wetting and final composite strength. An apparatus was designed that employs the classical sessile drop technique to determine contact angles while taking into consideration the ease of surface oxidation of molten pure Al. The effects of SiC oxidation and Mg addition on the wettability of SiC by molten Al were then studied experimentally. It was found that Al tends to wet SiC to a greater degree in the presence of a thin oxidation layer of silica, and that Mg added to the Al melt in quantities of 1 and 3 mass percent, significantly improves its wetting on SiC.

Composite laminates are optimized in order to maximize failure loads. In the optimization procedure, the effects of lamina orientation and lamina orientation with stiffness constraints are considered for laminates constructed of different numbers of lamina. Optimal failure characteristics are determined by systematically considering all possible lamina orientations in the laminate; thus, the optima determined are global optima. In the failure analysis, the quadratic tensor polynomial failure criterion is used for most of the investigations. However, some calculations are also performed for comparison using the maximum stress and maximum strain failure criteria. It is found that, for some biaxial applied load ratios, the optimized first ply failure is unaffected by a single stiffness constraint. Furthermore, it is shown that increasing the number of lamina in a laminate may or may not increase the maximum failure load per unit thickness. In most biaxial load cases, four-layer balanced laminates are shown to be optimal.

LOCATION OF IMPACT DAMAGE SITES IN COMPOSITE AIRCRAFT STRUCTURES, TASK 3.4.1 Final Report
Frank Karpala and Omer L. Hageniers Dec. 1992 19 p
(DSIS-94-01590; CTN-94-61258) Avail: CASI HC A03/MF A01

A portable field-level inspection system called D Sight was developed to isolate areas of a composite aircraft structure that may have been damaged by low-energy impact. An extensive laboratory program was set up to determine factors which influence the correlation between D Sight indication and subsurface delamination. The program also demonstrated the applicability of D Sight to the wide range of materials, lay-ups, coatings, and structures that are potentially inspectable. The D Sight concept was tested on CF-18 composite structures under in-service conditions, including a study of various paint schemes. A second phase of the project addressed the development and evaluation of an advanced development model leading to the definition of those factors important in a commercial product. The project verified that D Sight can detect low-energy impact damage in aircraft structures at a level below that detectable by normal human visual inspection. The project also resulted in a D Sight Aircraft Inspection System that can be used in field evaluations for further definition of the design needs of a field deployable impact damage inspection system. AN APPROXIMATE SOLUTION FOR INTERLAMINAR STRESSES IN LAMINATED COMPOSITES Ph.D. Thesis
Cheryl Angeline Rose 1992 193 p
Avail: Univ. Microfilms Order No. DA9316921

An approximate solution for interlaminar stresses in finite width laminated composites subjected to uniform extensional and bending loads is presented. The solution is based upon the principle of minimum complementary energy and an assumed, statically admissible stress state, derived by considering local material mismatch effects and global equilibrium requirements. The stresses in each layer are approximated by polynomial functions of the thickness coordinate, multiplied by combinations of exponential functions of the in-plane coordinate, expressed in terms of fourteen unknown decay parameters. Imposing the stationary condition of the laminate complementary energy with respect to the unknown variables yields a system of fourteen nonlinear algebraic equations for the parameters. Newton's method is implemented to solve this system. Once the parameters are known, the stresses can be easily determined at any point in the laminate. Results are presented for through-thickness and interlaminar stress distributions for angle-ply, cross-ply (symmetric and unsymmetric laminates), and quasi-isotropic laminates subjected to uniform extension and bending. It is shown that the solution compares well with existing finite element solutions and represents an improved approximate solution for interlaminar stresses, primarily at interfaces where global equilibrium is satisfied by the in-plane stresses, but large local mismatch in properties requires the presence of interlaminar stresses. Further, the contributions of both global equilibrium and local material mismatch effects to the stress field are clearly delineated. The results indicate that the significance of local mismatch effects is dependent on laminate stacking sequence. The demonstrated accuracy and efficiency of the solution make it ideally suited for parametric studies. Dissert. Abstr.

(ISBN-0-315-86546-6; CTN-94-61210) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Low velocity impact damage in carbon fiber polyether ether ketone (PEEK) thermoplastic composites was studied. The focus of the study was on the material properties that may control the extension of impact induced delamination (IID) and transverse cracks. The strength of materials (SoM) approach to predict the damage extension was evaluated by dynamic finite element analysis. A fracture mechanics approach is proposed to characterize the crack growth behavior of IID. Predicting delamination size is discussed using the concept of crack arrest toughness. In the crossply laminates studied, it was found that the PEEK exhibits the same damage modes as seen in thermoset epoxy composites. Considering the thermal residual stress and the crack constraining mechanism, the SoM approach could not predict extension of transverse cracks nor IID results from a Mode 2 dominated unstable fracture. IID occurs under displacement controlled conditions and seems to be arrested at constant interlaminar fracture energy. The strain energy release rate and the delamination arrest toughness of the material control the delamination extension. The end-loaded split fracture test was conducted to measure Mode 2 delamination toughness of the composite. Large deflection effects on toughness measurement were studied by nonlinear beam theory. The test was also used to measure Mode 2 crack arrest toughness. Author (CISTI)

TOUGHENING MECHANISMS IN FIBER-REINFORCED CERAMIC-MATRIX COMPOSITES Ph.D. Thesis
Elizabeth Patricia Butler 1993 242 p
Avail: Univ. Microfilms Order No. DA9325936

A single fiber bridging a crack at an angle of 90 degrees resulted in an increased fracture toughness of the composite over and above the intrinsic fracture resistance of the glass matrix of at least eight percent. The fracture resistance rose with increasing crack length, saturating at long crack lengths, indicating classic T-curve behavior arising from the mechanism of crack-wake bridging in which the predominant energy dissipation mechanism is frictional sliding of the fiber within the matrix. For high composite toughness the important interfacial properties are the interfacial toughness, G(sib IC), and the frictional shear resistance, tau (tau = q(sub 0) mu). A novel approach to interfacial property measurement allowed these factors to be deconvoluted for the first time. Independent measurements of the clamping stress and the friction coefficient verified these results. These interfacial parameters were found to be sensitive to composite processing; acid etching the carbon coating on the outer surface of the fiber before incorporation into the glass matrix doubled the steady maximum fracture toughness. Composites reinforced with an oxidized SiC fiber resulted in a maximum fracture resistance of 50 percent greater than that for the unreinforced glass matrix. These increases in interfacial shear resistance were due to an increase in the sliding friction coefficients; the clamping stresses were unchanged within experimental error. The effectiveness of ductile metal coatings for enhanced toughness was demonstrated using 6 micron and 19 micron copper fiber coatings. The copper coated fiber composites showed extensive T-curve behavior with a steady state toughness being reached that was 25 percent greater than the toughness of the unreinforced glass, independent of coating thickness. A new technique for measuring the interfacial shear resistances for fiber coatings sliding with respect to both the fiber and the matrix has been developed. This is the only experimental method available for such measurements. A procedure using classical fracture mechanics analysis has been developed in which the constitutive relationship for fiber bridging was deconvoluted from the experimentally measured fracture resistance curves. This allowed direct comparison of micromechanical properties to the macrofracture resistance of these fiber reinforced composites. Dissert. Abstr.

THEORY OF THICK, LAMINATED COMPOSITE SHALLOW SHELLS Ph.D. Thesis
Jin-Der Paul Chang 1992 361 p
Avail: Univ. Microfilms Order No. DA9307734

This dissertation presents the derivation of a generalized shell theory with shear deformation and rotary inertia in curvilinear coordinates that yields a set of tenth order differential equations in terms of five independent displacement functions and five boundary conditions upon an edge of a shell. This theory includes two radii of curvature of the normal section cut along the coordinate lines and one radius of twist, which can also be used for a shell having two principal radii of curvature by setting the radius of twist to be infinite. The theory of general shells in curvilinear coordinates based on Love's second approximation can be reduced to a theory based on Love's first approximation. By using the assumptions for shallow shells having a planform projection, a theory of shallow shells with shear deformation and rotary inertia in cartesian coordinates is obtained. Further assumptions are made if a very shallow shell is used. The shallow shell theory is reduced to a simplified shallow shell theory, i.e., a generalized Donnell shell theory with shear deformation and rotary inertia. The present shallow shell theory and simplified shallow shell theory are formulated by employing a set of generalized constitutive equations of laminae. Further, the energy functionals, strain energy, kinetic energy, and loading potentials of these theories are presented. Closed-form solutions are obtained in free vibration and static deflections, due to different loading, for isotropic and cross-ply laminated shell panels with shear diaphragm boundaries. Comparisons are made among the results of the most accurate of the present theories and other various shear deformation theories and those from the three dimensional elasticity theory, available in recently published papers. It shows that the theory developed here gives very accurate results. Furthermore, by using the three present theories based on different assumptions and the thin shallow shell theory, extensive studies are made for isotropic and laminated composite shells in analyses of static deflections and free vibrations. The limits of accuracy for the simplified one of the present theories and the thin shallow shell theory are shown in comparison with the most accurate present theory. The important effects of shear deformation and rotary inertia are also demonstrated. Also, the analysis of characteristic behavior of shells is included by using various parameters. This clearly demonstrates the various parametric effects. Dissert. Abstr.

FRACTURE MECHANICS AND MICROMECHANISMS IN FIBER-REINFORCED COMPOSITES Ph.D. Thesis
Shuh-Huei Li 1993 225 p
Avail: Univ. Microfilms Order No. DA9327242

The resistance to fracture of monolithic-brittle matrix or quasi-brittle matrix materials increases significantly by use of fibers. The objective of this thesis is to investigate the mechanisms dominating enhanced toughness of matrix due to the presence of fibers. A micromechanical model is

developed to study the stability and growth of a bridged crack in a semi-infinite, brittle matrix composite reinforced with unidirectional, continuous fibers. This model considers microfracture mechanisms which primarily involve debonding associated with frictional sliding along fiber-matrix interfaces, and matrix cracking during tensile loading. The bridging stress of fiber and bridging factor which characterizes the crack opening are presented in closed form. Based on Eshelby's inclusion method, the energy approach is used to describe various stages of fracture processes (crack initiation interfacial debonding, width-through crack at bend-over point, and sequential multiple cracking). To verify the validity of the theoretical model, an experimental study was conducted with cement-based composites made with different volume fractions of steel fibers. The techniques of optical fluorescence microscopy (OFM) and epoxy impregnation were used to study the internal debonding phenomena of composites. The extent of the debonding cracks were observed prior to the bend-over point (BOP). A 'stable growth' of the debonding crack, where the debonding length increases with applied load, was also investigated in the study. Comparisons of model predictions of debonding behavior with experimental data appear to support the validity of the model. A theoretical model is also developed to analyze failure mechanisms of randomly aligned, discontinuous fiber-reinforced brittle matrix composites. The micromechanisms of debonding/sliding along intact fibers and pull-out of fibers are taken into account. The influence of spatial distribution of fibers, fiber aspect ratio, and fiber volume fraction on the cracking stress and tensile strength of a composite are examined. Critical conditions for multiple fracture associated with strain-hardening behavior are discussed as well. The model was applied to glass and steel fiber cement-based composites and compared with available experimental results. Dissert. Abstr.

Current methods of lifetime assessment leave much to be desired. Typically, the expected life of a full-scale component exposed to a complex environment is based upon empirical interpretations of measurements performed on microscopic samples in controlled laboratory conditions. Extrapolation to the service component is accomplished by scaling laws, which, if used at all, are empirical; little or no attention is paid to synergistic interactions between the different components of the real environment. With the increasingly hostile conditions which must be faced in modern aerospace applications, improvement in lifetime estimation is mandated by both cost and safety considerations. This program aims at improving current methods of lifetime assessment by building in the characteristics of the micromechanisms known to be responsible for damage and failure. The broad approach entails the integration and, where necessary, augmentation of the micro-scale research results currently available in the literature into a macro-scale model with predictive capability. SODIUM SULFATE CORROSION OF SILICON CARBIDE FIBER-REINFORCED LITHIUM ALUMINOSILICATE GLASS-CERAMIC MATRIX COMPOSITES M.S. Thesis
Leopoldo C. Maldia Dec. 1993 71 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277224) Avail: CASI HC A04

Sodium sulfate hot corrosion of a SiC fiber-reinforced lithium aluminosilicate (LAS) glass-ceramic matrix composite was studied using Scanning Electron Microscope (SEM) and X-ray Diffraction (XRD). Changes in the microstructural chemical composition of the specimens were investigated. The samples provided by Naval Air Warfare Center (NAWC), Warminster, PA, were grouped as follows: (1) as-received, (2) Na2SO4 salt-coated and heat-treated in oxygen, (3) noncoated and heat-treated in oxygen, (4) Na2S4. Salt-coated and heat-treated in argon, and (5) noncoated and heat-treated in argon. Heat treatment was performed by NAWC for 100 hours at 900 C. Experimental data obtained indicated that the presence of Na2SO4 in an oxidative environment resulted in rapid corrosion of the matrix and SiC fibers and in the latter rings of SiO2 replaced what had previously been SiC. There was very limited degradation of the fibers and matrix exposed at the surface in the noncoated sample heat-treated in oxygen and in the salt-coated sample heat-treated in argon. A significant reduction in the amount of mullite in the matrices of all heat-treated samples was observed. Mullite dissolved into either the glassy phase or into the Beta-spodumene matrix. Lastly, the presence of distinct magnesium silicate crystalline phases in the salt-coated and heat-treated in oxygen sample implies that the MgO at the surface reacted with the SiO2 in the matrix. FINITE ELEMENT ANALYSIS OF DAMAGE IN FIBROUS COMPOSITES USING A MICROMECHANICAL MODEL M.S. Thesis
Joseph M. Berner Dec. 1993 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277226) Avail: CASI HC A05

The objective of this investigation is to study the damage mechanics of composite structures using a micromechanical approach for determining strength and stiffness degradation of the composite structures as damages, such as matrix cracking and fiber breakage, progress. The micromechanical cell method provides for analysis of stress at the fiber and matrix level while providing smeared composite properties for global structural analysis. As a result, the damage and failure criteria are expressed in terms of the fiber and matrix stress level of the composite structure. A correlation for stiffness reduction due to transverse cracking of a ceramic matrix composite under tensile loading is implemented in a three-dimensional finite element model. Next, thermal residual stresses from fabrication of the ceramic matrix composite are incorporated into the analysis. Finally, the finite element method is applied to a polymer matrix composite laminate with a center hole in order to study the progression of damage and final failure during tensile loading. The comparisons between the present predictions and the experimental results for the previous examples are very good. DTIC

BOND STRESS-SLIP CHARACTERISTICS OF FRP REBARS Interim Report, FY92 - FY93
L. J. Malvar Feb. 1994 51 p
(AD-A277191; NFESC-TR-2013-SHR) Avail: CASI HC A04/MF A01

The bond characteristics of four different types of glass fiber-reinforced plastic (GFRP) rebars with different surface deformations were analyzed experimentally. Local bond stress-slip data, as well as bond stress-radial deformation data, needed for constitutive modeling of the interface mechanics, were obtained for varying levels of confining pressure. In addition to bond stress and slip, radial stress and radial deformation were considered fundamental variables needed to provide for configuration-independent relationships. Each test specimen consisted of a 6 GFRP rebar embedded in a 3-inch-diameter, 4-inch-long cracked concrete cylinder subjected to a controlled, constant amount of confining axisymmetric radial pressure. Only 2.625 inches (the equivalent of five steel bar lugs) of contact were allowed between the bar and the concrete. For each rebar type, bond stress-slip and bond stress-radial deformation relationships were obtained for five levels of confining axisymmetric radial pressure. It was found that small surface indentations are sufficient to yield bond strengths comparable to that of steel bars. Effects of the deformations on tensile properties are discussed. It is also shown that radial pressure is an important parameter which can increase the bond strength threefold. DTIC

MECHANICS OF THE SINGLE FIBER PULLOUT PROBLEM WITH SEVERAL INTERFACE CONDITIONS Ph.D. Thesis
Kishore Venkateswara Pochiraju 1993 162 p
Avail: Univ. Microfilms Order No. DA9319730

The fiber-matrix interface in fiber reinforced ceramic matrix composites plays a key role not only in the load transfer between matrix and fiber, but also in the micro-damage initiation and growth mechanisms. Consequently, the interface affects the overall strength of the composite and its toughness properties. In this regard, the response of the single fiber pull-out (or indentation) model to the application of a load at the end of the fiber is commonly used as a rational means by which the mechanics of the interface can be studied. This thesis presents a rigorous analysis of the single fiber pull-out (or push-in) problem. An analytical/computational method is

developed to determine the stress fields in the model subject to several fiber-matrix interface conditions, including perfect bonding, frictional sliding, and interfacial cracking. The analysis initially focuses on the singular stress fields near the fiber protrusion point and/or at the open/sliding interfacial crack fronts. A local analysis is carried out using the Muskhelishvili - Kolosov complex potential method from which separable power type radial stress singularities and the associated stress field characteristics are sought. Through singular stress analysis, accurate description of the local stress fields can be obtained within a scaling factor. In order to obtain the scaling factor in the local region and accurate stresses in the rest of the model, a refined finite element analysis is conducted with prescribed loading and boundary constraints. This global analysis provides the detailed stress fields throughout the model. A local-global stress matching is then conducted to determine the region in which a perfect match is observed between the spatial distributions of stresses obtained from the local analysis and the finite element analysis. This local-global matching procedure provides the scaling factor in the local field, thus completing the determination of the total stress field. Applying this local-global matching procedure, the characteristics of the stress fields are examined for several physical models. A simulation of frictional sliding problem of fiber is conducted based on Coulomb's law for frictional contact. Dissert. Abstr.

HONEYCOMB SANDWICH STRUCTURES: VENTED VERSUS UNVENTED DESIGNS FOR SPACE SYSTEMS Final Report, Sep. 1992 - Oct. 1993
George Epstein and Susan Ruth Oct. 1993 24 p
(Contract F04701-88-C-0089)
(AD-A276713; TR-93(3904)-1; SMC-TR-94-02) Avail: CASI HC A03/MF A01

Several space systems programs have experienced significant anomalies associated with failures of unvented honeycomb sandwich structures. Based on documentation and personal experience, this report provides descriptions of the structures involved, the circumstances of the failures, and corrective actions. Of special note, it is concluded that failures occur due to internal pressure when the external environment is reduced in ambient pressure. Such failures are initiated at weak bond areas (presumed to result from a manufacturing defect - areas that were not previously identified/repaired). Once initiated, separation of the skin-to-core bond propagates very rapidly and has been described as explosive. It is recommended that honeycomb structures for space systems be adequately vented whenever possible. In situations where venting is not feasible, a series of recommendations is presented to minimize the likelihood of failure. Design and manufacturing parameters are listed for honeycomb sandwich panels that are not fully vented, in order to reduce the likelihood of failure. DTIC

ASSESSMENT OF IMPACT DAMAGE IN COMPOSITE STRUCTURES
R. Jones, S. C. Galea, and J. J. Paul Dec. 1993 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277063; ARL-TR-23; DODA-AR-008-409) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In order to provide through-life support for structural components fabricated from advanced composite materials, it is desirable to establish a damage tolerance methodology. There are many difficulties in meeting this objective, including the multiplicity of failure modes, the numerous types of potentially significant defects which may arise during manufacture or in service, and the sensitivity to moisture and temperature. This paper focuses on the problem of impact damage and reviews research undertaken at ARL in recent years related to the analysis and testing of impact damage composite laminates. It is shown that the residual strength of impact damaged laminates reduces to an asymptotic limit as the size of the damage increases and that uniaxial S-N curves for damaged laminates have a generic shape with a pronounced threshold (endurance) level. (AD-A277397; AFOSR-94-0072TR) Avail: CASI HC A11

Results of a three-year research effort aimed at developing an understanding of the factors controlling transverse strength and failure of intermetallic composites are presented. Experiments were conducted involving several aluminide matrix composites; two types of fibers were used in order to allow for large as well as small residual stresses. On the basis of the in situ observations and with the aid of high resolution strain mapping, the relevant damage mechanisms were identified. The experimental effort coupled with analytical models led to a number of conclusions that are important for the proper design of such composites. Among the important properties are the strength and sliding resistances of the interface, residual stresses, and fiber spacing. Therefore, optimum strength is achieved with either strongly bonded interfaces, or interfaces that debond easily but have large resistance to circumferential sliding. The latter condition could also be compatible with the requirement of debonding and relatively easy frictional sliding for maximum benefit from fiber reinforcement in longitudinal properties. The results suggest a potential benefit from having anisotropic interfacial properties, perhaps obtained through morphology, to allow easy sliding in the axial direction and more strongly resisted sliding in the circumferential direction. EFFECTS OF INTERPHASES ON THE MECHANICAL, THERMAL AND HYGROMECHANICAL RESPONSE OF FIBER-REINFORCED COMPOSITES Ph.D. Thesis
Heung Soap Choi 1993 270 p
Avail: Univ. Microfilms Order No. DA9327174

The effects of fiber-matrix interphases on the micro- and macro-mechanical properties of unidirectionally fiber-reinforced composites have been studied for composites subjected to transverse uniaxial, biaxial and shear loadings, uniform temperature changes and uniform changes of moisture concentration. The interphases have been modeled by the spring-layer model which accounts for continuity of tractions, but allows radial and circumferential displacement jumps across the interphase that are linearly related to the normal and tangential tractions. Numerical calculations in basic cells have been carried out using the boundary element method. For the isothermal case the results display the effects of variation of interphase stiffness on the fields of stress and deformation and on the effective elastic constants for square array, 45 deg rotated square array and hexagonal array composites with and without interphase failure and radial matrix cracking. For a hexagonal array, under the assumption that the failure mechanisms follow the periodicity of the composite, the stress intensity factors at the tip of L-shaped and perpendicular-shaped matrix cracks and the reduction of the effective elastic moduli due to the matrix cracks and interphase damage have been calculated and the conditions for matrix crack propagation and extension of interphase damage have been analyzed. A fiber with a reduced interphase stiffness contained in a unidirectionally fiber reinforced composite gives rise to higher stresses at its interphase as well as at the interphases of neighboring fibers. For a hexagonal array composite, detailed numerical results are presented. Three cases have been investigated: (1) a perfect composite, (2) a perfect composite which contains a single fiber with a lower interphase stiffness, (3) a perfect composite which contains a single fiber with interphase cracks and a lower interphase stiffness. The effects of the interphases on the distribution of residual stresses induced by a uniform temperature change have also been investigated. The influence of thermally induced residual stresses on the micro- and macro-mechanical strength and stiffness properties of a hexagonal array composite subjected to monotonically increasing uniaxial transverse loading have been studied. Finally, the hygro-mechanical behavior for a uniform specific moisture concentration has been investigated by using the analogy between temperature and moisture effects. Dissert. Abstr.

MECHANICS OF CRACKING FOR COMPOSITE MATERIAL Ph.D. Thesis
Shrwai Ho 1992 145 p
Avail: Univ. Microfilms Order No. DA9317170

Cracking in the system is responsible for the reduction of strength for the vast majority of engineering materials. The object of this thesis is to introduce the Linear Elastic Fracture Mechanics to discuss the state of

knowledge on the cracking behavior of Composite Materials. This has implications for the science of the subject - basic understanding and modeling - and for practical considerations to aid high performance engine development. Several models were proposed in this study. Tunneling, a commonly observed cracking process, is inspected in this thesis: a new model for tunneling crack is introduced. Formula for steady-state energy release rate G(sub ss), which make it convenient for finite element analyses, is presented, and the relevance of G(sub ss) is studied. The concept is applied to micro cracking in brittle matrix composites caused by thermal expansion mismatch and tunneling cracks in a laminated 0/90 ceramic/matrix composite. Comparisons between experiment results and modeling are also included. Another more practical concern is trying to reconcile design practices for ductile alloys and monolithic ceramics, and thereby provide a theoretical link between design with and of ceramic-matrix composites. For a monolithic panel, even a small hole reduces the load-carrying capacity by a factor of 3: this is notch-sensitive. For a ductile alloy a small hole does not reduce much the load-carrying capacity: this is notch-insensitive. The main goal of that study is to determine the maximum load-carrying capacity of a ceramic-matrix composite panel with a hole. The basic model is large-scale bridging. Bridging laws shape, width, and periodic effects are all discussed in the thesis. An extended model, two-level-bridging model, is also included. Most engineering composite components exhibit failure behaviors that are governed by anisotropic and heterogeneous characteristics. In this thesis, a spatial rescaling was found to reduce plane elasticity problems for orthotropic materials. Guided by this technique and other analytic results, a systematic analysis is conducted for fracture specimens to investigate the role of material orthotropy in fracture behavior of unidirectional composites. All numerical calibrations are presented with fitting formulas in the relevant parameter regimes. The effect of material orthotropy on fracture behavior of unidirectional composites is thus quantified. Dissert. Abstr.

A continuum theory with a micro-macro structure was developed for composite laminates that satisfies the traction and displacement continuity requirements at interfaces. The interlaminar stresses were included in the model in a natural way and without any ad hoc assumptions. The built-in microstructure of the continuum model can account for the effects of curvature and geometric nonlinearity. A set of constitutive relations in terms of material properties of individual constituents was developed which is capable of modeling fiber orientation and stacking sequence. The theory was further expanded to include the effects of temperature where a set of coupled thermomechanical field equations with corresponding constitutive relations were derived. Development of the theory for cylindrical and spherical geometries was completed and wave motions in flat and curved geometries was studied. A layerwise shear-deformable multi-director C(sup 0) finite element formulation for the theory was developed which accounts for three dimensional effects, allows thickness variation, and permits the warping of the deformed normal, while satisfying all continuity requirements. Volume 1 includes the micro-macro continuum model of composite laminates as well as linear theory and wave motions in cylindrical and sperical laminates. DTIC

A THERMAL VISCOELASTIC ANALYSIS FOR THICK-WALLED COMPOSITE CYLINDERS

Larry S. Chien and Jerome T. Tzeng 18 Mar. 1994 39 p

(AD-A274143; ARL-TR-310) Avail: CASI HC A03/MF A01

The linear quasistatic thermal viscoelastic behavior of a three dimensional thick laminated composite cylinder is investigated. The cylinder is loaded with a temperature change; however, thermomechanical coupling effects are neglected. The correspondence principle is employed to convert the thermoviscoelastic problem to its corresponding thermoelasticity problem in Laplace transform space. A closed-form formulation is then developed for each layer, assuming a state of generalized plane strain, to solve for a general solution of the corresponding thermoelastic problem. The Laplace transformed solution is completed by satisfying boundary conditions at the inner and outer surfaces of the cylinder and continuity conditions between adjacent layers. The solution process is expedited by replacing two undetermined coefficients in the assumed form of the thermoelastic solution with the normal stresses at the inner and outer of the cylinder and satisfying the continuity conditions between adjacent layers. Finally, direct Laplace transform inversion is used to yield the quasistatic thermoviscoelastic solution. DTIC

Carbon fiber reinforced silicon carbide matrix composites (C/SiC) were made by a process termed Supercritical Fluid Infiltration. A preceramic polymer, e.g., a polycarbosilane which can pyrolyze to form SiC, is dissolved in a supercritical fluid, the solution conveyed into a tightly woven preform of carbon fiber, and the preceramic polymer caused to deposit in the interstitial volume surrounding the fibers. Subsequent pyrolysis of the polymer forms the SiC matrix and fiber coating. Supercritical propane at conditions of 140 deg C, 4000 psi dissolves polycarbsilane to a concentration level of 30% (w/w), a level that results on substantial infiltration and deposition of the polymer. The yield of SiC from the parent polymer upon pyrolysis was determined to be about 50% (w/w); the polymer was fractionated using supercritical propane (in a process termed increasing pressure profiling), and it was found that some of the low molecular weight fractions gave extremely low yields of SiC (less than 25%) whereas some of the high molecular weight fractions yielded over 80% SiC. When the parent polymer was used for the infiltration studies the deposited material was modular in appearance suggesting that the liquid low molecular weight portion of the polymer was predominately and adversely influencing the uniformity. The physical properties of in-situ produced composites, such as the TEOS-polysiloxane based systems, are directly related to the complex interaction of structural features from the nanoscopic to macroscopic scales. The nature of these structural interactions are a key element in understanding and controlling mechanical properties in these systems. We believe that the smallest scale structures, in the nanometer range, correlate with properties such as the modulus while large-scale structures on the micron scale effect failure in these materials. This paper discusses techniques for analysis of structural features and interrelation of structural features over these wide ranges of size using small-angle light, x-ray and neutron scattering. Combination of data from different instruments allows for characterization of the interaction between these different size scale features. DOE

Multilayer laminates of Al 6090/SiC/25p MMC and Al 5182 were prepared by hot pressing alternating layers of the component materials at 450 C in an argon gas atmosphere. Tensile properties, interlayer normal and shear bond strengths, and fracture toughness were measured in the T6-treated and untreated conditions. Fracture toughness was also measured as a function of the volume fraction of the MMC component. Yield and tensile strengths increased substantially by the T6 treatment while the total-elongation and interlayer bond strengths decreased even more substantially. Fracture toughness, on the other hand, did not change appreciably by the T6 treatment. The fracture toughness increased perceptibly with an increase in the volume percent of the MMC component. DOE

METCAN DEMONSTRATION MANUAL, VERSION 1.0 Final Report
H.-J. Lee and P. L. N. Murthy Apr. 1992 131 p
(RTOP 510-01-50)
(NASA-TM-105607; E-6944; NAS 1.15:105607) Avail: CASI HC A07/MF A02

The various features of the Metal Matrix Composite Analyzer (METCAN) computer program to simulate the high temperature nonlinear behavior of continuous fiber reinforced metal matrix composites are demonstrated. Different problems are used to demonstrate various capabilities of METCAN for both static and cyclic analyses. A complete description of the METCAN output file is also included to help interpret results. Author

Efforts focused on the use of thermoplastic composite materials in the development of structural details associated with an advanced fighter fuselage section with applicability to transport design. In support of these designs, mechanics developments were conducted in two areas. First, a dissipative strain energy approach to material characterization and failure prediction, developed at the Naval Research Laboratory, was evaluated as a design/analysis tool. Second, a finite element formulation for thick composites was developed and incorporated into a lug analysis method which incorporates pin bending effects. Manufacturing concepts were developed for an upper fuel cell cover. A detailed trade study produced two promising concepts: fiber placement and single-step diaphragm forming. Based on the innovative design/manufacturing concepts for the fuselage section primary structure, elements were designed, fabricated, and structurally tested. These elements focused on key issues such as thick composite lugs and low cost forming of fastenerless, stiffener/moldine concepts. Manufacturing techniques included autoclave consolidation, single diaphragm consolidation (SDCC) and roll-forming. Author

Relationships between manufacturing costs and design details must be understood to promote the application of advanced composite technologies to transport fuselage structures. A team approach, integrating the disciplines responsible for aircraft structural design and manufacturing, was developed to perform cost and weight trade studies for a twenty-foot diameter aft fuselage section. Baseline composite design and manufacturing concepts were selected for large quadrant panels in crown, side, and keel areas of the fuselage section. The associated technical issues were also identified. Detailed evaluation of crown panels indicated the potential for large weight savings and costs competitive with aluminum technology in the 1995 timeframe. Different processes and material forms were selected for the various elements that comprise the fuselage structure. Additional cost and weight savings potential was estimated for future advancements. The autoclave based THERM-X(sub R) process was evaluated by cocuring complex curved panels with frames and stiffeners. The process was shown to result in composite parts of high quality with good compaction at sharp radius regions and corners of intersecting parts. The structural properties of the postbuckled panels fabricated were found to be equivalent to those of conventionally tooled hand laid-up parts. Significant savings in bagging time over conventional tooling were documented. Structural details such as cocured shear ties and embedded stiffener flanges in the skin were found to suppress failure modes such as failure at corners of intersecting members and skin stiffeners separation. (Grant NAG3-1270; RTOP 505-62-10)
(NASA-CR-195303; E-8705; NAS 1.26:195303) Avail: CASI HC A04/MF A01

Global/local method in conjunction with a special macro finite element is used to gain computational efficiency in the simulation of textile composites behavior. Results are included to demonstrate the effectiveness of the method. Also, 2D finite elements are used to study boundary effects in plain weave composite specimens subjected to extension, shear, and flexure loads. Effective extension, shear, and flexural moduli were found to be quite sensitive to specimen size. For extension and flexure loads stress distributions were affected by a free surface, but the free surface boundary effect did not appear to propagate very far into the interior. For shear load, the boundary effect appeared to propagate much further into the interior. The report is in the form of two technical articles, the first describes

the global/local method while the second describes the use of the 2D finite elements. Author (revised)

COMPARISON OF THE COMPRESSIVE STRENGTHS FOR STITCHED AND TOUGHENED COMPOSITE SYSTEMS
James R. Reeder Apr. 1994 46 p
(RTOP 505-63-50-04)
(NASA-TM-109108; NAS 1.15:109108) Avail: CASI HC A03/MF A01

The compression strength of a stitched and a toughened matrix graphite/epoxy composite was determined and compared to a baseline unstitched untoughened composite. Two different layups with a variety of test lengths were tested under both ambient and hot/wet conditions. No significant difference in strength was seen for the different materials when the gage lengths of the specimens were long enough to lead to a buckling failure. For shorter specimens, a 30 percent reduction in strength from the baseline was seen due to stitching for both a 48-ply quasi-isotropic and a (0/45/0/-45/90/-45/0/45/0)s laminate. Analysis of the results suggested that the decrease in strength was due to increased fiber misalignment due to the stitches. An observed increasing strength with decreasing gage length, which was seen for all materials, was explained with a size effect model. The model assumed a random distribution of flaws (misaligned fibers). The toughened materials showed a small increase in strength over the baseline material for both laminates presumably due to the compensating effects of a more compliant matrix and straighter fibers in the toughened material. The hot/wet strength of the stitched and baseline material fell 30 percent below their ambient strengths for shorter, nonbuckling specimen, while the strength of the toughened matrix material only fell 20 percent. Video images of the failing specimen were recorded and showed local failures prior to global collapse of the specimen. These images support the theory of a random distribution of flaws controlling composite failure. Failed specimen appearance, however, seems to be a misleading indication of the cause of failure. This report summarizes progress on fatigue crack growth through unidirectional SCS-6/titanium alloy composites and the fatigue and fracture of ceramic matrix composites reinforced with continuous fibers, both large and small, in unidirectional and woven forms. The fiber/matrix interaction is detailed for SCS-6/titanium alloy composites near stress concentrations, and it is shown how that is similar to measurements of fiber stress in the wake of fatigue cracks. The main theme of the work on ceramic matrix composites is the effect of fiber architecture on fatigue behavior. DTIC

(Contract N00014-89-J-1459)
(AD-A277672) Avail: CASI HC A03/MF A01

We have shown in earlier work that significant improvements upon the mechanical properties of the alumina + 15 w/o zirconia (PRD-166) fiber/borosilicate glass matrix and mullite (Nextel 480 and 550) fiber/mullite matrix composites could be achieved using interface engineering approach. This approach involves a control of the microstructure, roughness of the interface, and the thermal expansion mismatch between the fiber and matrix in order to improve the strength and fracture toughness of the composite. We have made a qualitative comparison of the elemental distribution in the PRD-166/glass (N51A) composites, with and without an SnO2 coating, on fibers using secondary ion mass spectrometry (SIMS). The results confirmed that tin dioxide serves as an effective barrier between this fiber and the silica-based glass. The tensile strength and toughness of the interface between SnO2 and flat alumina substrate were obtained by a laser spallation technique. DTIC

The conference papers are presented. The Advanced Composite Technology (ACT) Program is a major multi-year research initiative to achieve a national goal of technology readiness before the end of the decade. Conference papers recorded results of research in the ACT Program in the specific areas of automated fiber placement, resin transfer molding, textile preforms, and stitching as these processes influence design, performance, and cost of composites in aircraft structures. These papers will also be included in the Ninth Conference Proceedings to be published by the Federal Aviation Administration as a separate document. For individual titles, see N94-33122 through N94-33137.

A conceptual and preliminary designers' cost prediction model has been initiated. The model will provide a technically sound method for evaluating the relative cost of different composite structural designs, fabrication processes, and assembly methods that can be compared to equivalent metallic parts or assemblies. The feasibility of developing cost prediction software in a modular form for interfacing with state of the art preliminary design tools and computer aided design programs is being evaluated. The goal of this task is to establish theoretical cost functions that relate geometric design features to summed material cost and labor content in terms of process mechanics and physics. The output of the designers' present analytical tools will be input for the designers' cost prediction model to provide the designer with a data base and deterministic cost methodology that allows one to trade and synthesize designs with both cost and weight as objective functions for optimization. The approach, goals, plans, and progress is presented for development of COSTADE (Cost Optimization Software for Transport Aircraft Design Evaluation). Author

An automated data abstraction form (ADAF) was developed to collect information on advanced fabrication processes and their related costs. The information will be collected for all components being fabricated as part of the Advanced Composite Technology (ACT) program and included in a COmposites INformation System (COINS) data base. The aim of the COINS development effort is to provide future airframe preliminary design and

fabrication teams with a tool through which production cost can become a deterministic variable in the design optimization process. The effort was initiated by NASA Langley to implement the recommendations of a working group comprised of representatives from the commercial airframe companies. The principal working group recommendation was to reinstitute collection of composite part fabrication data in a format similar to the DOD/NASA Structural Composites Fabrication Guide. The fabrication information collection form was automated with current user friendly computer technology. The new automated form and features that make the form easy to use by an aircraft structural design manufacturing team are described. Author

Fuselage structures for transport aircraft represent a large portion of both the weight and cost of these aircraft primary structures. Composite materials offer the potential for reducing both the weight and cost of these structures, but only limited studies of the response and failure of composite fuselage structures have been conducted. The research is described which is being conducted and planned at NASA Langley to understand the critical behavior of composite fuselage structures and to validate the structural mechanics methodology being developed for stiffened composite fuselage shell structure subjected to combined internal pressure and mechanical loads. Stiffened shell and curved stiffened panel designs are currently being developed and analyzed, and these designs will be fabricated and then tested to study critical fuselage behavior and to validate structural analysis and design methodology. The research includes studies of the effects of combined internal pressure and mechanical loads on nonlinear stiffened panel and shell behavior, the effects of cutouts and other gradient producing discontinuities on composite shell response, and the effects of local damage on pressure containment and residual strength. Scaling laws are being developed that relate full scale and subscale behavior of composite fuselage shells. Author

STRUCTURAL TESTING OF THE TECHNOLOGY INTEGRATION BOX BEAM

C. F. Griffin *In* NASA. Langley Research Center, Second NASA Advanced Composites Technology Conference Jun. 1992 p 85-97 (For primary document see N94-33121 09-24)

Avail: CASI HC A03/MF A04

A full scale section of a transport aircraft wing box was designed, analyzed, fabricated, and tested. The wing box section, which was called the technology integration box beam, contained blade stiffened covers and T-stiffened channel spars constructed using graphite-epoxy materials. Covers, spars, and the aluminum ribs were assembled using mechanical fasteners. The box beam was statically tested for several loading conditions to verify the stiffness and strength characteristics of the composite wing design. Failure of the box beam occurred at 125 pct. of design limit load during the combined unbending and torsion ultimate design load test. It appears that the failure initiated at a stiffener runout location in the upper cover which resulted in rupture of the upper cover and portions of both spars. Author

Avail: CASI HC A03/MF A04

Composite structures have the potential to be cost effective, structurally efficient primary aircraft structures. As part of the Advanced Composite Technology (ACT) program to exploit this potential for heavily loaded aircraft structures, the design and fabrication of the technology integration box beam (TIBB) was completed. The TIBB is an advanced composite prototype structure for the center wing section of the Lockheed C-130 aircraft. The TIBB was tested for downbending, upbending, torsion, and combined upbending and torsion load conditions to verify the design. The TIBB failed at 83 percent of design ultimate load for the combined upbending and torsion load condition. Current analytical and experimental results are described for a study of the mechanisms that led to the failure of the TIBB. Experimental results include load, strain, and deflection data. An analytical study was conducted of the TIBB structural response. Analytical results include strain and deflection results from a global analysis of the TIBB. Derived from text

DEVELOPMENT OF STITCHED/RTM COMPOSITE PRIMARY STRUCTURES

Susan M. Kullerd (Lockheed Engineering and Sciences Co., Hampton, VA.) and Marvin B. Dow *In its* Second NASA Advanced Composites Technology Conference Jun. 1992 p 115-140 (For primary document see N94-33121 09-24)

Avail: CASI HC A03/MF A04

The goal of the NASA Advanced Composites Technology (ACT) Program is to provide the technology required to gain the full benefit of weight savings and performance offered by composite primary structures. Achieving the goal is dependent on developing composite materials and structures which are damage tolerant and economical to manufacture. Researchers at NASA Langley and Douglas Aircraft Co. are studying stitching reinforcement combined with resin transfer molding (RTM) to create structures meeting the ACT program goals. The research is aimed at materials, processes, and structural concepts for application in both transport wings and fuselages. Empirical guidelines are being established for stitching reinforcement in primary structures and test data are reported in another paper. New data are presented herein from evaluation tests of thick (96 ply) and thin (16 ply) stitched laminates and from selection tests of RTM composite resins. Tension strength, compression strength, and post impact compression strength data are reported. Elements of a NASA Langley program to expand the science base for stitched/RTM composites are discussed. Derived from text

Poe, Jr., and C. E. Harris *In its* Second NASA Advanced Composites Technology Conference Jun. 1992 p 197-238 (For primary document see N94-33121 09-24)
(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

Transport fuselage structures are designed to contain pressure following a large penetrating damage event. Application of composites to fuselage structures requires a data base and supporting analysis on tension damage tolerance. Tests with 430 fracture specimens were used to accomplish the following: (1) identify critical material and laminate variables affecting notch sensitivity, (2) evaluate composite failure criteria, and (3) recommend a screening test method. Variables studied included fiber type, matrix toughness, lamination manufacturing process, and intraply hybridization. The laminates found to have the lowest notch sensitivity were manufactured using automated tow placement. This suggests a possible relationship between the stress distribution and repeatable levels of material inhomogeneity that are larger than found in traditional tape laminates. Laminates with the highest notch sensitivity consisted of toughened matrix materials that were resistant to a splitting phenomena that reduces stress concentrations in load bearing plies. Parameters for conventional fracture criteria were found to increase with the crack length of the smallest notch sizes studied. Most materials and laminate combinations followed less than a square root singularity for the largest crack sizes studied. Specimen geometry, notch type, and notch size were evaluated in developing a screening test procedure. Results indicate that a range of notch sizes must be tested to determine notch sensitivity. LOCAL DESIGN OPTIMIZATION FOR COMPOSITE TRANSPORT FUSELAGE CROWN PANELS
G. D. Swanson, L. B. Ilcewicz, T. H. Walker, D. Graesser, M. Tuttle, and Z. Zabinsky *In* NASA. Langley Research Center, Second NASA Advanced Composites Technology Conference Jun. 1992 p 243-262 (For primary document see N94-33121 09-24)
(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

Composite transport fuselage crown panel design and manufacturing plans were optimized to have projected cost and weight savings of 18 and 45 percent, respectively. These savings are close to those quoted as overall NASA Advanced Composite Technology (ACT) program goals. Three local optimization tasks were found to influence the cost and weight of fuselage crown panels. The effects are summarized of each task and the task associated with a design cost model is described in detail. Studies were performed to evaluate the relationship between manufacturing cost and design details. A design tool was developed to aid in these studies. The development of the design tool included combining cost and performance constraints with a random search optimization algorithm. The resulting software was used in a series of optimization studies that evaluated the sensitivity of design variables, guidelines, criteria, and material selection on cost. The effect of blending adjacent design points in a full scale panel subjected to changing load distributions and local variations was shown to be important. Technical issues and directions for future work were identified. Author (revised)

Avail: CASI HC A03/MF A04

Commercial fuselage structures contain significant challenges in attempting to save manufacturing costs with advanced composite technology. Assembly issues, materials costs, and fabrication of elements with complex geometry are each expected to drive the cost of composite fuselage structure. Key technologies, such as large crown panel fabrication, were pursued for low cost. An intricate bond panel design and manufacturing concept were selected based on the efforts of the Design Build Team. The manufacturing processes selected for the intricate bond design include multiple large panel fabrication with Advanced Tow Placement (ATP) process, innovative cure tooling concepts, resin transfer molding of long fuselage frames, and use of low cost materials forms. The process optimization for final design/manufacturing configuration included factory simulations and hardware demonstrations. These efforts and other optimization tasks were instrumental in reducing costs by 18 pct. and weight by 45 pct. relative to an aluminum baseline. The qualitative and quantitative results of the manufacturing demonstrations were used to assess manufacturing risks and technology readiness. Author (revised)

RECENT PROGRESS IN NASA LANGLEY RESEARCH CENTER TEXTILE REINFORCED COMPOSITES PROGRAM
H. Benson Dexter, Charles E. Harris, and Norman J. Johnston *In its* Second NASA Advanced Composites Technology Conference Jun. 1992 p 295-323 (For primary document see N94-33121 09-24)
Avail: CASI HC A03/MF A04

Research was conducted to explore the benefits of textile reinforced composites for transport aircraft primary structures. The objective is to develop and demonstrate the potential of affordable textile reinforced composite materials to meet design properties and damage tolerance requirements of advanced aircraft structural concepts. Some program elements include development of textile preforms, processing science, mechanics of materials, experimental characterization of materials, and development and evaluation of textile reinforced composite structural elements and subcomponents. Textile 3-D weaving, 3-D braiding, and knitting and/or stitching are being compared with conventional laminated tape processes for improved damage tolerance. Through-the-thickness reinforcements offer significant damage tolerance improvements. However, these gains must be weighted against potential loss in in-plane properties such as strength and stiffness. Analytical trade studies are underway to establish design guidelines for the application of textile material forms to meet specific loading requirements. Fabrication and testing of large structural parts are required to establish the potential of textile reinforced composite materials. Author

Innovative design concepts and cost effective fabrication processes were developed for damage tolerant primary structures that can perform at a design ultimate strain level of 6000 micro inch/inch. Attention focused on the use of textile high performance fiber reinforcement concepts that provide improved damage tolerance and out-of-plane load capability, low cost resin film infusion (RFI) and resin transfer molding (RTM) processes, and thermoplastic forming concepts. The fabrication of wing 'Y' spars by four different materials and/or processes methods is described: fabricated using IM7 angle interlock 0 to 90 deg woven preforms with + or - 45 deg plies stitched with Toray high strength graphite thread and processed using RFI and 3501-6 epoxy; fabricated using G40-800 knitted/stitched preforms and processed using RFI and 3501-6 epoxy; fabricated using G40-800 knitted/stitched preforms using RTM and Tactix 123/H41 epoxy; and fabricated preforms using AS4(6K)/PEEK 150 g commingled angle interlock 0 to 90 deg woven preforms with + or - 45 deg commingled plies stitched using high strength graphite thread and processed by consolidation. Structural efficiency, processability, and acquisition cost are compared. Author

Avail: CASI HC A03/MF A04

Braided composite materials has been recognized as a potential cost effective material form for fuselage structural elements. Consequently, there is a strong need for more knowledge in the design, manufacture, test, and analysis of textile structural composites. Advance braided composite technology is advanced towards applications to a large commercial transport fuselage. The mechanics are summarized of materials and manufacturing demonstration results which were obtained in order to acquire an understanding of how braided composites can be applied to a commercial fuselage. Textile composites consisting of 2-D, 2-D triaxial, and 3-D braid patterns with thermoplastic and two resin transfer molding resin systems were studied. The structural performance of braided composites was evaluated through an extensive mechanical test program. Analytical methods were also developed and applied to predict the following: internal fiber architecture; stiffness; fiber stresses; failure mechanisms; notch effects; and the history of failure of the braided composite specimens. The applicability of braided composites to a commercial transport fuselage was further assessed through a manufacturing demonstration. Author

STRUCTURAL INTEGRITY OF INTELLIGENT MATERIALS AND STRUCTURES Report, 1 Jul. 1993 - 31 Jan. 1994
Warren C. Gibson and Bryce L. Fowler 25 Feb. 1994 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-C-0026)
(AD-A278397; AFOSR-94-0166TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Intelligent materials open new avenues to improve performance, reliability, and longevity of future aerospace vehicle structures by allowing the materials themselves to become active elements for multiple system functions. However, the application of intelligent materials and structures has been inhibited because the effects of microstructural interactions between intelligent and host material elements have heretofore not been well characterized. This research implemented and applied three analytical approaches to the study of stress concentrations and cracking around embedded sensor/actuator elements. One was an analytical method based on high-order Ritz functions for accurate representation of steep strain gradients. The second was a conventional finite element approach using very fine meshes, and the third was a finite-element-based computation of energy release rates suitable for predicting crack growth. Among other interesting results, the analyses compared the effects of applied loads with the effects of actuation strains and found that the applied loads were more likely to cause cracking or delamination than actuation. ON THE MECHANICS OF MICROBALLOON-REINFORCED METAL MATRIX COMPOSITES
M. Y. He and F. W. Zok Apr. 1994 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-I-0224)
(AD-A277928) Avail: CASI HC A03

The elastic/plastic response of ceramic microballoon reinforced metal matrix composites subject to uniaxial loading are examined using finite element analysis. The microballoons are assumed to be spherical and their morphology characterized by the ratio of wall thickness, t, to radius, R. The key parameters investigated are the relative wall thickness, t/R, the modulus ratio (matrix/ceramic) and the yield and hardening characteristics of the matrix. The emphasis of the study is on the overall stress-strain response of the composite, the development of matrix plasticity and the development of stress within the microballoon. Author (DTIC)

FUEL PROPERTY EFFECTS ON ENGINE COMBUSTION PROCESSES
N. P. Cernansky 10 Jan. 1994 2 p
(Contract DE-FG04-87AL-44658)
(DE94-005529; DOE/AL-44658/T2) Avail: CASI HC A01/MF A01

Our engine studies have concentrated on 2 areas of interest to autoignition and emissions from engines. In the first, we investigated the effect of nitric oxide (NO) on the reactivity and autoignition behavior of 87 PRF. In the second study, we continued work on the effects of blending ethers on the reactivity and autoignition of a primary reference fuel blend, 87 PRF, with emphasis placed on the chemical interactions between ethers and the baseline fuel. The effects of nitric oxide (NO) on the reactivity and autoignition behavior of 87 PRF were examined in our research engine under motored conditions at compression ratios of 5.2 and 8.2. The most significant conclusions of our study are: (1) nitric oxide does interact with the hydrocarbon oxidation at conditions typically experienced by the end gas in a fired engine; (2) the effect is complex and, depending on the reaction environment, the same concentration of NO can produce dramatically different results. These results are particularly important given the fact that residual fractions and recycled exhaust gases in spark ignited engines typically result in about 200-600 ppm of NO in the unburned charge. The octane enhancing ethers, MTBE, ETBE, TAME, and DIPE, were blended into 87 PRF at a constant 0 atom fraction of 1.94% in the fuel mixtures and the mixtures were tested under motored conditions at our new compression ratio of 8.2. This new compression ratio allows studies on autoignition behaviors of 87 PRF with and without ethers. The results showed that, when using 87 PRF/ether mixtures, reactivity was significantly reduced as indicated by the higher inlet temperature required to initiate reactivity, significantly lower maximum CO concentration and the significantly higher inlet temperature required for autoignition. AN AXIAL APPROACH TO DETECTION IN CAPILLARY ELECTROPHORESIS Ph.D. Thesis
J. A. Taylor May 1993 131 p
(Contract W-7405-eng-82)
(DE94-005556; IS-T-1656) Avail: CASI HC A07/MF A02

Our approach involves on-axis illumination of the compounds inside the capillary detection region and is applied to absorbance and fluorescence detection. Absorbance measurements were made by focussing an incident laser beam into one capillary end; by using signals collected over the entire length of analyte band, this enhances the analytical path length of conventional absorbance detection 60x. This instrument offers a 15x improvement in detection limits. Three fluorescence detection experiments are discussed, all of which involve insertion of an optical fiber into the capillary. The first uses a high refractive index liquid phase to obtain total internal reflectance along capillary axis, this reducing light scatter. The second uses a charge-coupled device camera for simultaneous imaging of a capillary array (this may be useful in genome sequencing, etc.). The third is a study of fluid motion inside the capillary under pressure-driven and electroosmotic flow. The thesis is divided into four parts. DOE

INFRARED SPECTROELECTROCHEMICAL STUDY OF CYANIDE ADSORPTION AND REACTIONS AT PLATINUM ELECTRODES IN AQUEOUS PERCHLORATE ELECTROLYTE
Kevin Ashley, Daniel L. Feldheim, Diane B. Parry, Mahesh G. Samant, and Michael R. Philpott 18 Feb. 1994 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-C-0173)
(AD-A276402; TR-07) Avail: CASI HC A03

In situ infrared (IR) spectroelectrochemistry is used to investigate the behavior of cyanide (CN) at polycrystalline platinum surfaces in aqueous perchlorate (CLO4(-)) electrolyte. IR spectroelectrochemical data reveal the existence of a number of surface, as well as solution, cyanide species in the interfacial region. Within the double-layer potential region, there is IR evidence for several forms of absorbed cyanide. When the potential is made sufficiently positive, cyanide is oxidized to form cyanate. Other solution cyanide species which may be formed at the platinum-cyanide solution interface include hydrogen cyanide and square planar platinum cyanide complex. Author (DTIC)

EMPIRICAL AND SEMI-EMPIRICAL RELATIONSHIPS OF LIQUID-VAPOR, SOLID-VAPOR, AND SOLID-LIQUID SURFACE ENERGIES Final Report
William E. Frazier 1 Sep. 1993 28 p
(AD-A276480; NAWCADWAR-93053-60) Avail: CASI HC A03/MF A01

Surface energy, frequently referred to as surface tension, plays a critical role in materials processing and the evolution of a material's microstructure and properties. Processes critically dependent upon surface energy include casting, rapid solidification processes, flotation separation, smelting, degassing of liquid metals and solidification processing to name a few. However, despite its technological importance, there is a dearth of credible surface energy data available for most alloys and a number of elements. This paper serves as a compilation of useful data and presents correlations that may be used to estimate surface energy. DTIC

The effect of germanium on the hot electron current of metal-oxide-semiconductor devices has been studied by avalanche electron injection from the silicon to silicon dioxide. Different doses of germanium ranging from 10(exp 12) to 10(exp 15) atoms/sq cm are implanted into Si-SiO2 interface. The lucky hot electron population is suppressed by germanium implantation. We have used the charge-voltage technique to measure the interface state density. The interface state density increase caused by Ge implantation is negligible if the dose is lower than 10(exp 14) Ge/sq cm. We have also used different implantation energies to locate the Ge peak at different locations in the Si. We found that when the peak is at Si-SiO2 interface, the hot electron population is the lowest. Our results show that Ge implantation is a promising method to solve the hot carrier problem that has become important in submicrometer devices. DTIC

SHOCK TUBE IGNITION AND COMBUSTION OF ALUMINUM/MAGNESIUM ALLOY PARTICLES IN OXYGEN AT HIGH PRESSURE Ph.D. Thesis
Ted Anthony Roberts 1993 320 p
Avail: Univ. Microfilms Order No. DA9329149

The ignition and combustion of Al, Mg, and Al/Mg alloy particles in 99 percent O2/1 percent N2 mixtures is investigated at high temperatures and pressures for rocket engine applications. The 20 micron particles contain

0, 5, 10, 20, 40, 60, 80, and 100 weight percent Mg alloyed with Al, and are ignited in oxygen using the reflected shock in a shock tube near the endwall. Using this technique, the ignition delay and combustion times of the particles are measured at temperatures up to 3250 K as a function of Mg content for oxygen pressures of 8.5, 17, and 34 atm. An ignition model is developed which employs a simple lumped capacitance energy equation and temperature and pressure dependent particle and gas properties. Good agreement is achieved between the measured and predicted trends in the ignition delay times. For the particles investigated, the contribution of heterogeneous reaction to the heating of the particle is found to be significant at lower temperatures, but may be neglected at gas temperatures above 3000 K. As little as 10 percent Mg reduces the ignition delay time substantially at all pressures tested. The particle ignition delay times decrease with increasing Mg content, and this reduction becomes less pronounced as oxidizer temperature and pressure are increased.

INTERACTION OF WATER WITH METAL SURFACES
Sheng-Bai Zhu and Michael R. Philpott 18 Feb. 1994 32 p
(Contract N00014-92-C-0173)
(AD-A276260; TR-08) Avail: CASI HC A03/MF A01

A new class of potential suitable for modeling the adsorption of water on different metal sites is described. The new potentials are simple in form and convenient for use in computer simulations. In their real space form they comprise three parts: a pair-wise sum of spatial anisotropic 12-6 potentials, a pair-wise-sum of isotopic short range potentials, and an image potential. Two modifications of the potential are developed. In the first, the anisotropic potential acts only on the oxygen atom and not on the protons. In the second, the potential acts on all the atoms of the water molecule. In practical calculations it is convenient to transform the potential to a reciprocal space form in the manner described by Steele. DTIC

INFRARED AND NEAR INFRARED TRANSIENT ABSORPTION SPECTROSCOPY OF MOLECULAR FREE RADICALS
T. J. Sears, M. Wu, G. E. Hall, B. C. Chang, G. Hansford, J. C. Bloch, and R. W. Field 1993 8 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 13-23 Jan. 1993
(Contract DE-AC02-76CH-00016)
(DE94-005446; BNL-49888; CONF-930159-59) Avail: CASI HC A02/MF A01

The advantages of absorption spectroscopy at low absorbances include a linear relationship between signal size and number of absorbing molecules, line of sight measurement, and easily interpretable lineshape functions. The main disadvantage is due to the necessity of measuring a small change in light intensity, usually in the presence of a strong background, which limits the sensitivity. In this work, recent results obtained using absorption techniques with continuous wave lasers to measure vibrational and electronic spectra in the mid- and near-infrared of small free radicals are reported. The radical of interest was generated by excimer laser photolysis of a chemically stable precursor molecule and detected by measuring the transient decrease in power of a continuous wave probe laser that traversed the photolyzed volume before being imaged onto a detector. IGNITION STUDIES IN NONPREMIXED HYDROGEN/AIR COMBUSTION
Final Report
Chung K. Law and Thomas G. Kreutz 24 Jan. 1994 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-90-G-0222)
(AD-A275954; ARO-27565.3-EG) Avail: CASI HC A03

Ignition in nonpremixed counterflowing jets of fuel against heated air has been investigated experimentally, computationally, and analytically. Using H2/air ignition as the primary test system, the dominant chemical kinetics of ignition has been identified as well as the role of temperature, pressure, aerodynamic straining, and fuel concentration on the ignition process. In addition, the coupling of mass transport and aerodynamic straining to the chemical kinetics in nonpremixed ignition has been clarified. The methodologies developed for investigating hydrogen/air ignition have been extended to ignition of more complex and realistic fuels such as methane, n-butane, and isobutane. DTIC

IMAGING AMS
S. P. H. T. Freeman (Oxford Univ., England.), C. B. Ramsey (Oxford Univ., England.), and R. E. M. Hedges (Oxford Univ., England.) Dec. 1993 13 p Presented at the 6th International Conference on Accelerator Mass Spectrometry, Canberra, Australia, 17 Sep. - 1 Oct. 1993
(Contract W-7405-eng-48)
(DE94-006662; UCRL-JC-115791; CONF-930960-9) Avail: CASI HC A03/MF A01

The benefits of simultaneous high effective mass resolution and large spectrometer acceptance that accelerator mass spectrometry has afforded the bulk analysis of material samples by secondary ion mass spectrometry may also be applied to imaging SIMS. The authors are exploring imaging AMS with the addition to the Oxford (sup 14)C-AMS system of a scanning secondary ion source. It employs a sub micron probe and a separate Cs flood to further increase the useful ion yield. The source has been accommodated on the system by directly injecting sputtered ions into the accelerator without mass analysis. They are detected with a range of devices including new high-bandwidth detectors. Qualitative mass spectra may be easily generated by varying only the post-accelerator analysis magnet. Selected ion signals may be used for imaging. In developing the instrument for bioscience research the authors are establishing its capability for measuring the lighter elements prevalent in biological tissue. Importantly, the machine can map the distributions of radiocarbon labeled compounds with an efficiency of about 1(per thousand). A background due to misidentification of non-(sup 14)C ions as a result of the reduced ion mass filtering is too small to hinder high magnification microscopy. DOE

AMS BEYOND 2000
J. C. Davis 28 Dec. 1993 15 p Presented at the 6th International Conference on Accelerator Mass Spectrometry, Canberra, Australia, 17 Sep. - 1 Oct. 1993
(Contract W-7405-eng-48)
(DE94-006666; UCRL-JC-114145; CONF-930960-8) Avail: CASI HC A03/MF A01

The occasion of this conference, the Sixth International Conference on Accelerator Mass Spectrometry, falls sixteen years after the remarkable triple simultaneous discovery of this powerful isotopic measurement. In the interval since the Fifth Conference in Paris in 1991, new facilities of both large and small size have become fully operational, achieving impressive gains in both measurement throughput and precision. The purpose of this short review is to extrapolate from recent gains and experience and to project the status of the field beyond the coming millennial date. AMS achieved instant application in archaeology and the geosciences and its early growth was stimulated by the excitement caused by the early results. The ability to obtain an accurate radiocarbon date with a sample one thousand times smaller than possible with scintillation or gas counting, the ability to trace (sup 14)CO2 in sea water with a similar thousand fold shrinkage in sample size, and the wide utility of (sup 10)Be, (sup 26)Al, (sup 36)Cl, and (sup 129)I as tracers and chronometers of erosion, hydrology and paleoclimate were sufficient to drive the partial conversion of existing accelerators and the construction of new dedicated ones. These applications remain the core of the present field and continue to justify its growth. The past few years, however, have seen developments in new fields. Biomedicine, chemical kinetics, materials science, forensic dosimetry, and arms control/counter proliferation have been explored. These applications have varying promise and will influence development of AMS programs in new ways in the future. DOE

TURBULENCE STRUCTURE OF A PREMIXED FLAME IN A COAXIAL FREE AIR JET IN THE PRESENCE OR ABSENCE OF A BASE FLOW Ph.D. Thesis
Roland Alan Cusworth 1992 316 p
(ISBN-0-315-78739-2) Avail: Univ. Microfilms Order No. DANN78739

The base region surrounding the nozzle exit plane of rockets has a strong influence on the structure of the hot turbulent exhaust plume. It has also been established that numerical simulations of such flows are strongly dependent on the turbulence model employed. The present experimental study is an attempt and to provide benchmark data on the turbulence structure of this type of flow, for turbulence model validation purposes and to shed some light into the base region effect. The real flow situation of interest is modelled in the laboratory by a premixed hydrogen/air flame in a co-flowing air in the presence or absence of a base region between the central and annular jets. The main experimental diagnostic tool used is an Argon-ion, two-dimensional (two-color) laser Doppler velocimeter, with a relevant data acquisition and processing system. Mean axial and radial velocities, as well as the three turbulence intensities and shear intensity were obtained along the centerline and nine cross-sections of the flow. A two control volume arrangement was used to measure direct correlations of the axial fluctuating velocities from which the axial turbulence macro-scale was derived. The macro-scale and the measured turbulence kinetic energy provide experimental data on the dissipation rate of the turbulence kinetic energy, an important constituent variable in all turbulence models, which has been neglected in almost all previous experimental investigations. The results obtained indicate that, in a fuel-rich exhaust plume, the temperature would increase due to promotion of secondary combustion by the base, and thus increase both infrared radiation emissions and microwave attenuation in the vicinity of the nozzle exit. In the case of a fuel-lean flame, downstream of the base flow region the temperature would be suppressed due to the strong influx of cold surrounding air, and thus reduce the production of infrared radiation and microwave attenuation. Due to the lack of a low velocity recirculation zone, secondary combustion in the nonbase fuel rich exhaust plume is less likely to occur; but, the nonbase exhaust may produce a longer detectable infrared signal, since the temperature in the thermal layer decreases more slowly than in the case of the base flame.

COMBUSTION-RELATED STUDIES USING WEAKLY-BONDED COMPLEXES
R. A. Beaudet Jun. 1993 26 p
(Contract DE-FG03-89ER-14053)
(DE94-006632; DOE/ER-14053/T5) Avail: CASI HC A03/MF A01

This work is concerned with microscopic-level phenomena of importance in combustion. Weakly bonded adducts formed in supersonic expansions are investigated spectroscopically and used to limit the angles and impact parameters of biomolecular encounters. Also examined are species in which a free radical such as oxygen is bonded to a stable molecule in a shallow well outside the reaction barrier. These species can be used for several studies such as those involving photoinitiated reactions. The main experimental approach uses tunable diode laser absorption spectroscopy to monitor and characterize in detail the complexes of interest, and laser photoinitiation and LIF/MPI detection to examine biomolecular processes in which the adducts are used as precursors. In the first phase of this research, geometries and other molecular properties are being determined from vibrational-rotational spectra. In the second phase, these complexes will be used as precursors to study photoinitiated reactions in precursor geometry limited environments. DOE

The authors have been constructing a special purpose small angle neutron scattering spectrometer (SAND) in collaboration with IPNS of Argonne National Laboratory and Texaco Research Laboratories in Beacon, New York. The spectrometer, having a moderate neutron flux, will be uniquely suited for detailed studies of complex fluids in their various phases. This spectrometer will be fully available to general users of the small angle scattering community after a year of testing and upon installation of the auxiliary equipment. The general research objective of the MIT group is to continue studies of the microstructural relationship to phase-behavior in three-component microemulsion systems. Specifically, they shall study the (1) variation of bulk structures when a microemulsion undergoes a non-wetting to wetting transition, (2) correlating interfacial reflectivity measurements of these wetting transitions to the SANS results, (3) use the contrast variation technique they recently developed for measuring the mean and Gaussian curvatures of the surfactant sheet to study the structural inversion of water-in-oil to oil-in-water microemulsions and the transition of disordered bicontinuous microemulsion to ordered lamellar phases, (4) investigation of the effects of spatial confinement on the phase behavior and structure of bicontinuous microemulsions, and finally (5) they shall continue the study of the recently discovered non-exponential relaxation of droplet density fluctuations near the critical and percolation points in water-in-oil droplet microemulsions. ELECTROCHEMICAL SURFACE MODIFICATION OF SILICON MONOCRYSTALS: A SURFACE ANALYTIC EXAMINATION Ph.D. Thesis [ELEKTROCHEMISCHE OBERFLAECHENMODIFIZIERUNG VON SILIZIUMEINKRISTALLEN: EINE OBERFLAECHEANALYTISCHE UNTERSUCHUNG]
Thomas Bitzer 1992 157 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95733) Avail: Issuing Activity (European Space Agency (ESA))

After photoelectrochemical processing, the n-silicon monocrystals are characterized using X-ray and ultraviolet photoelectron spectroscopy, diffraction of low energy electrons and high resolution electron energy loss spectroscopy. A combined electrochemistry/ultrahigh vacuum system was specially developed. Electronic properties, stochiometry and morphology of differently oriented silicon electrodes during the electrochemical erosion of an electrolytic oxide film in aqueous ammonium fluoride solutions are examined ex situ with good time resolution. The correlation of the anodic dark current with the structure of the silicon/electrolyte interface was discussed. The influence of electrolyte chemical composition and pH value on hydrogen termination is investigated and a model of dynamic behavior of dark current was developed. The hydrogenation of (111) oriented silicon surfaces was optimized and a process for electrochemical preparation of atomic Si(111)-1 by 1:H surfaces is presented. The electronic structure of electrochemically synthesized surface was characterized by ultraviolet photoelectron spectroscopy and compared with band structure calculation results. ESA

OXIDE PIGMENTS IN WATER: THE COLLOID-CHEMICAL POINT OF VIEW Ph.D. Thesis
S. G. J. Heijman 16 Jun. 1993 163 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148616) Avail: Issuing Activity (National Technical Information Service (NTIS))

The effect of polyacrylic acid type dispersing agents on the stability against coagulation of titanium dioxide particles in water is investigated. Because polyacrylic acid is a charged polymer, two mechanisms are important: electrostatic stabilization and steric stabilization. At low salt concentrations the electrostatic stabilization is the most important mechanism. During the drying process of the paint film, the ionic strength is increasing and consequently the electrostatic stabilization is decreasing. Under these circumstances the additional steric stabilization is necessary to prevent coagulation. Two methods are evaluated in order to measure

the hydrodynamic layer thickness of the adsorbed polymer layer. Because the layer is relatively thin (3 nm), the methods normally used to measure the hydrodynamic layer thickness are not applicable. The hydrodynamic layer thickness is an indication for the steric stabilization properties of a dispersing agent. Electrostatic stabilization of the pigment dispersion can be quantified by measuring the zeta potential of the dispersion. A combination of both parameters gives an indication of the working mechanism of a dispersing agent. NTIS

PREPARATION OF CATALYST PARTICLES USING METHODS OF COLLOID CHEMISTRY. PART 1: PREPARATION OF SILICA PARTICLES FROM ALCOHOL SOLUTIONS
R. Lindberg 29 Sep. 1993 31 p
(PB94-135597; ISBN-951-22-1761-9) Avail: CASI HC A03/MF A01

Monodisperse silica particles ranging from 50 to 1500 nm in diameter with a standard deviation of 2 to 15 percent can be precipitated from tetraethyl orthosilicate (TEOS) in aqueous ethanol solutions containing ammonia. Three reactions are generally used to describe the hydrolysis and condensation of silicon alkoxides: hydrolysis, alcohol condensation, and water condensation. Final particle size is dependent on the silicon alkoxide and alcohol. Particles prepared in methanol solutions are the smallest and the particle size increases with increasing chain length of the alcohol. Influence of ammonia, water, and TEOS concentrations on the particle size, monodispersity, and aggregation of particles is presented. NTIS

A MODEL OF CONCURRENT FLOW FLAME SPREAD OVER A THIN SOLID FUEL Ph.D. Thesis
Paul Vincent Ferkul 1993 157 p
Avail: Univ. Microfilms Order No. DA9321871

A numerical model is developed to examine laminar flame spread and extinction over a thin solid fuel in low-speed concurrent flows. The model provides a more precise fluid-mechanical description of the flame by incorporating an elliptic treatment of the upstream flame stabilization zone near the fuel burnout point. Parabolic equations are used to treat the downstream flame, which has a higher flow Reynolds number. The parabolic and elliptic regions are coupled smoothly by an appropriate matching of boundary conditions. The solid phase consists of an energy equation with surface radiative loss and a surface pyrolysis relation. Steady spread with constant flame and pyrolysis lengths is found possible for thin fuels and this facilitates the adoption of a moving coordinate system attached to the flame with the flame spread rate being an eigenvalue. Calculations are performed in purely forced flow in a range of velocities which are lower than those induced in a normal gravity buoyant environment. Both quenching and blowoff extinction are observed. The results show that as flow velocity or oxygen percentage is reduced, the flame spread rate, the pyrolysis length, and the flame length all decrease, as expected. The flame standoff distance from the solid and the reaction zone thickness, however, first increase with decreasing flow velocity, but eventually decrease very near the quenching extinction limit. The short, diffuse flames observed at low flow velocities and oxygen levels are consistent with available experimental data. The maximum flame temperature decreases slowly at first as flow velocity is reduced, then falls more steeply close to the quenching extinction limit. Low velocity quenching occurs as a result of heat loss. At low velocities, surface radiative loss becomes a significant fraction of the total combustion heat release. In addition, the shorter flame length causes an increase in the fraction of conduction downstream compared to conduction to the fuel. These heat losses lead to lower flame temperatures, and ultimately, extinction. This extinction mechanism differs from that of blowoff, where the flame is unable to be stabilized due to the high flow velocity. Dissert. Abstr.

A NUMERICAL METHOD FOR MIXING/CHEMICALLY REACTING COMPRESSIBLE FLOW WITH FINITE RATE CHEMISTRY Ph.D. Thesis
Vinh That Ton 1993 172 p
Avail: Univ. Microfilms Order No. DA9318724

An efficient and accurate numerical method is presented to solve conservation laws for time-dependent multicomponent flows of compressible reactive gaseous mixtures with and without finite rate chemical reactions. An essentially non-oscillatory (ENO) shock capturing scheme for solving hyperbolic equations is extended to solve this system of conservation laws in a fully coupled way. The thermodynamic properties of the mixture are modeled accurately in the extension. The stiff chemical kinetic terms are split from the fluid motion by the fractional step algorithm. A complex chemical kinetic system with finite rate chemistry is used in the calculation to study transient combustion processes. A new technique for proper treatment of the stiff source terms is utilized, so that a correct solution of stiff combustion waves can be obtained even for large time steps and grid sizes. Numerical difficulties associated with contact surfaces for multicomponent mixing flow and stiffness of detonation wave problems are eliminated. Several test problems of one and two space dimensions, inviscid and viscous, with and without chemical reactions, are presented. A numerical study of the mechanism for enhancement of mixing and combustion with potential applications to scramjet combustor design is presented. Dissert. Abstr.

SOLID SURFACE (Videotape)
Dec. 1992 Videotape: 7 min. 5 sec. playing time, in color, with sound
(NASA-TM-109746; NONP-VT-94-9946) Avail: CASI VHS A01/BETA A22

This video tape describes the development of the Solid Surface Combustion Experiment (SSCE) by researchers at NASA LeRC. The experiment studies fire spreading over a small solid fuel sample subjected to microgravity conditions in Earth orbit. Buoyant convection, which determines the heat transfer in fires on Earth, disappears in microgravity; hence, this experiment will help researchers understand how fires act on Earth. CASI

DETERMINATION OF BPSG THIN-FILM PROPERTIES USING IR REFLECTION SPECTROSCOPY OF PRODUCT WAFERS
T. M. Niemczyk (New Mexico Univ., Albuquerque.), J. E. Franke (New Mexico Univ., Albuquerque.), Liz-Hong Zhang (New Mexico Univ., Albuquerque.), D. M. Haaland, and K. J. Radigan 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-94AL-85000)
(DE94-006591; SAND-93-1635C; CONF-931108-77) Avail: Issuing Activity (Department of Energy (DOE))

Borophosphosilicate glass (BPSG) thin films are widely used in the microelectronics industry as passivation layers, planarization layers, low-fusion-temperature dielectrics, etc. Currently available analytical methods for determining boron and phosphorus content in BPSG films do not meet the demands of at-line or in-situ quality control process monitoring. Infrared (IR) spectroscopy satisfies many of the at-line or in-situ issues, but has

only recently been capable of providing quantitative results using undoped and unpatterned silicon substrates. Three BPSG calibration sets were analyzed using infrared external reflection-absorption spectroscopy: (1) 21 films deposited on undoped silicon coated with 0.1 micron of silicon dioxide, (2) 21 films deposited on undoped silicon, and (3) 9 films deposited on microelectronics product wafers. A multivariate partial least squares analysis of the spectral data for the first large data set showed that boron content, phosphorus content, and film thickness can be quantified with precisions of 0.10 wt%, 0.12 wt%, and 30 A, respectively. The second large data set yielded similar results. The precisions obtained for the nine product wafer samples were 0.13 wt%B, 0.09 wt%P, and for film thickness 103 A.

CONDENSED-PHASE PROCESSES DURING SOLID PROPELLANT COMBUSTION. 3: PRELIMINARY DEPTH-PROFILING STUDIES ON XM39, JA2, M9, M30, AND HMX2 Final Report, Nov. 1990 - Oct. 1991
Michael A. Schroeder, Robert A. Fifer, Martin S. Miller, Rose A. Pesce-Rodriguez, and Claire J. Selawski Jan. 1994 30 p
(DA Proj. 1L1-61102-AH-43)
(AD-A276595; ARL-TR-346) Avail: CASI HC A03/MF A01

This report describes preliminary depth-profiling studies on the chemical changes in the burned layers of propellant samples that have been burned in air then quenched by dropping them into water. The changes described here are mainly those observable by infrared spectroscopy using an infrared microscope. Depth-profiling is obtained either by examining the cross section of a burned propellant sample or by abrasive blasting small amounts of material from the burned surface and examining the remaining surface in the infrared microscope. The propellants and compositions studied include XM39, JA2, M9, M30, and HMX2. For the nitramine-binder compositions XM39 and HMX2, the surface layers seem to consist of a layer of molten oxidizer (RDX or HMX) tens to hundreds of micrometers thick, overlaid by a 10- or 20-micrometer-thick layer of binder and/or its decomposition products. In the case of the nitrate ester compositions JA2 and M9, the chemical changes observable by infrared spectroscopy seem to be very near the surface, within approximately 10 micrometers. This is in agreement with our scanning electron microscope observations and with results in the literature.

ANALYSIS OF FORWARD AND INVERSE PROBLEMS IN CHEMICAL DYNAMICS AND SPECTROSCOPY
H. Rabitz 1993 9 p
(Contract DE-FG02-86ER-13480)
(DE94-007607; DOE/ER-13480/4) Avail: CASI HC A02/MF A01

During the past year, progress was made in exploring the relation of between chemical mechanisms and resultant combustion behavior, and the relation between potential surface features and dynamical observables. The first category of study also included theory of lumping or simplification of complex kinetic mechanisms. A systematic approach is being developed understanding and practical execution of kinetic models, including with transport In the second area of research on potential surfaces, we are exploring forward analysis of how potential features influence laboratory observable cross sections and rate constants, as well as development of inverse analysis algorithms. In the latter category, considerable progress has been made on developing an algorithm which is stable and capable of reliably inverting high resolution laboratory spectroscopic data back to intramolecular potentials. A collaboration is under way in this case, with the laboratory program of Marsha Lester, and preliminary results indicate that high quality potential surfaces can be extracted in this fashion. DOE

SOME PERSPECTIVES ON SOLUTION-PHASE ELECTRON-TRANSFER PROCESSES
Joseph T. Hupp and Michael J. Weaver Feb. 1994 56 p
(Contract N00014-91-J-1409)
(AD-A276906; TR-145) Avail: CASI HC A04/MF A01

The kinetics of electron-transfer (ET) process is a subject graced by a remarkable diversity as well as importance in chemistry and biology. Of the manifold types of chemical ET reactions, those occurring in solution and at electrode-solution interfaces have been the subject of a notably concerted and fruitful research effort. This activity was in large part spawned, and subsequently spurred, by the development of the theoretical treatments by Rudy Marcus and others, now broadly know as 'Marcus theory.' The happy circumstances that enabled the formulation of such quantitative theoretical relationships for solution-phase ET kinetics having true predictive and interpreatative value have acted as a considerable impetus to the development of an increasingly diverse and impressive range of experimental activities.

ELECTRICAL COMMUNICATION BETWEEN GLUCOSE OXIDASE AND ELECTRODES BASED ON POLY(VINYLIMIDAZOLE) COMPLEX OF Os(bpy)2Cl2 Technical Report, Oct. 1992 - Dec. 1993
Ravi Rajagopalan, Timothy J. Ohara, and Adam Heller 17 Feb. 1994 23 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276585) Avail: CASI HC A03

Glucose oxidase was electrically wired to glassy carbon electrodes by redox hydrogels based on poly(N-vinyl imidazole) (PVI) complexed with Os(bpy)2Cl2 (PVI-Os). The hydrogels were formed by crosslinking PVI-Os and glucose oxidase with poly(ethylene glycol) diglycidyl ether (PEGDGE). Glucose was electrooxidized on the PVI-Os based wired enzyme electrodes at 350 mV versus SCE. The dependence of the electrooxidation current on pH, ionic strength, film thickness, weight fraction of the enzyme in the redox hydrogel, and oxygen partial pressure for electrodes rotating at 1000 rpm is described.

SOFT X RAY PHOTOELECTRON SPECTROSCOPY STUDY OF THE INTERACTION OF Cr WITH MoS2(0001)
Thomas D. Durbin, Jeffrey R. Lince, Stephen V. Didziulis, David K. Shuh, and Jory A . Yarmoff 14 Jan. 1994 42 p
(Contract F04701-88-C-0089)
(AD-A276916; TR-93(3935)-2; SMC-TR-94-06) Avail: CASI HC A03/MF A01

The solid lubricant MoS2 must exhibit good adhesion to high-Cr steels used in moving mechanical assemblies on spacecraft to provide an effective antiwear lifetime. The adhesion can be maximized by tailoring the interfacial reactivity between the Cr at the steel surface and MoS2. To this end, we studied the interaction of Cr with the MoS2(0001) surface with core-level and valence-band soft x ray photoelectron spectroscopy employing synchrotron radiation (hv=150 to 400 eV). Cr vapor-deposited at room temperature formed relatively flat films on MoS2(0001). The Cr underwent a limited chemical reaction with the MOS2 substrate to form a chromium sulfide and Mo metal. The Mo metal formed a thin layer between the Cr film and the MoS2 substrate. In contrast, reacted S was incorporated throughout the Cr film, with its concentration enhanced at the surface. Annealing the Cr-covered sample drove the reaction between Cr and MoS2, forming additional Mo metal that alloyed with Cr, and several adsorbed S species on the Cr film surface. Annealing also caused partial coalescence of the Cr-containing portion of the film, uncovering parts of the Cr-Mo alloy. The reactivity of Cr with respect to MoS2(0001) is greater than that of Fe and somewhat less than that of Mn. The results indicate that cleaning the surface of a steel device before MoS2 film deposition will expose bare Fe and Cr metal, which could increase the metal/lubricant adhesion.

CONTROL EXPERIMENTS IN LIQUID METAL COMBUSTION
T. R. Ogden and L. A. Parnell Feb. 1994 11 p
(AD-A276918) Avail: CASI HC A03/MF A01

This paper describes control experiments in liquid metal combustion. Preliminary results are reported for the effectiveness of open-loop control techniques in improving closed-cycle liquid metal combustion. The effects of non-axisymmetric nozzle shapes and pulsed oxidant flow rate on the combustion process are tested by measuring the total fuel utilization at the point of end-of-run pressurization, which is characteristic of this type of combustor, and by observing the jet/bath dynamics using X-radiography. Nozzle geometry and oxidant flow rate are the parameters used to control the combustion process. The reacting jet stability and rate of end-of-run pressurization is affected somewhat by the nozzle geometry however, no significant effect is observed on the total fuel utilization achieved. Pulsed

oxidant injection produces an expected large effect in bath/jet dynamics as the oxidant flow rate is pulsed from 3 to 20 gr/sec, but no statistically significant change in total utilization is demonstrated. The causes of combustion chamber pressurization during the combustion process and at end-of-run are discussed. In an effort to explain significant pressurization of the combustion chamber developed during the combustion process, chamber pressure dependence on oxidant purity grade, oxidant flow rate and hydrogen content are reported. The presence of relatively small amounts of hydrocarbons introduced during combustor fabrication produces significant pressurization of the combustion chamber throughout the combustion period, while the chamber pressure has relatively little dependence on the oxidant mass flow rate or oxidant purity. No significant effect of pressurization caused by hydrocarbons on maximum fuel utilization is observed. DTIC

(Contract DE-AC05-84OR-21400)
(DE94-007224; CONF-9304148-2) Avail: CASI HC A03/MF A01

Monte Carlo computer codes have been independently developed at several laboratories for performing calculations of radiolysis of water. The different codes involve a wide variety of models and related assumptions in treating the many physical and chemical processes that occur. Because few detailed aspects of such computations can be directly checked by experiment, it is important to make comparisons of various predicted microscopic distributions. This paper compares results obtained with codes developed at Lawrence Berkeley Laboratory and at Oak Ridge National Laboratory. Both codes were used to calculate the spatial distributions of various radical species in spurs along the tracks of energetic electrons. Similarities and differences in the results of this preliminary study are shown. Additional work is planned. DOE

This program of research was to develop spectroscopic and kinetic methods for exploring chemical structure and molecular dynamics at interfaces between dielectric solids and liquids. The research was carried out using fluorescence and vibrational spectroscopy from probe molecules where spectral and temporal differences in emission, absorption, or scattering provide information about the surface onto which they are adsorbed or bound. Studies focused on the interfacial chemistry of insulating surfaces in contact with liquids. The spectral and temporal response of bound or adsorbed molecules were used to observe differences in the chemical environment at the liquid-solid interface. Time resolution was also valuable in sorting out heterogeneous surface environments from differences in emission rate constants, adsorption rates, and reaction kinetics. DTIC

(DE94-007030; LBL-34669) Avail: CASI HC A17/MF A04

The economics of producing carboxylic acids by fermentation is often dominated, not by the fermentation cost, but by the cost of recovering and purifying the acids from dilute aqueous solutions. Experiments were performed to measure uptakes of lactic and succinic acids as functions of pH by basic polymeric sorbents; sorbent regeneration was also tested. Performance at pH greater than pK(sub a) and regenerability depend on sorbent basicity; apparent pK(sub a) and monomer pK(sub a) can be used to predict sorbent performance. Two basic amine extractants, Alamine 336 and Amberlite LA-2, in were also studied; they are able to sustain capacity to higher pH in diluents that stabilize the acid-amine complex through H bonding. Secondary amines perform better than tert-amines in diluents that solvate the additional proton. Competitive sulfate and phosphate, an interference in fermentation, are taken up by sorbents more strongly than by extractants. The third step in the proposed fermentation process, the cracking of the trimethylammonium (TMA) carboxylate, was also examined. Because lactic acid is more soluble and tends to self-esterify, simple thermal cracking does not remove all TMA; a more promising approach is to esterify the TMA lactate by reaction with an alcohol. VOLATILES COMBUSTION IN FLUIDIZED BEDS
R. P. Hesketh and R. A. Pendergrass 1993 40 p
(Contract DE-FG22-92PC-92539)
(DE94-008382; DOE/PC-92539/5) Avail: CASI HC A03/MF A01

The goal of this project is to investigate the conditions in which volatiles will burn within both the dense and freeboard regions of fluidized beds. Experiments using a fluidized bed operated at incipient fluidization will be performed to characterize the effect of particle surface area, initial fuel concentration, and particle type on the inhibition of volatiles within a fluidized bed. The work conducted during the period 4 September, 1993 through 3 December, 1993 is reported in this technical progress report. The experimental work during this time period consists primarily of reactor start-up and data collection. Results of stoichiometric combustion of propane in air at three temperatures and a residence time of approximately 3 s are reported. The results of a detailed chemical kinetic model of propane and methane are reported for the theoretical work for this quarter. These results give further evidence that the inhibition of propane and methane combustion is caused by the sand particles. DOE

The recent successful adaptation of mainline computational chemistry codes to parallel computers introduces a new era of cost-effective, computer-intensive chemistry applications and paves the way for future applications on massively parallel centralized computers being developed under the High Performance Computer and Communications Initiative. Parallel computer architecture offers the promise of inexpensive supercomputing for the price of effort in algorithm adaptations to parallelism. In chemical sciences-supported work at Argonne, beginning efforts at algorithm changes in computational chemistry codes has resulted in program performances on the group's 12-processor Alliant computer superior to that on one-processor Cray X-MP or Y-MP computers. The effort so far has focused on sophisticated and highly accurate electronic structure

production codes for determining the forces between atoms and molecules responsible for chemical structure, spectra, and reactivity. Some effort has also been invested in trajectory simulations of molecular dynamics. The American-made Alliant computer (model FX/2812) is one of the latest generation of shared-memory group or division size computers that generally cost about an order of magnitude less than the laboratory or university size computers such as Crays. SURFACE PROBES OF POROUS TOLUENE/WATER ICES: ADSORPTION KINETICS AND ANNEALING SPECTRA MEASURED BY SECOND HARMONIC GENERATION

Bryan F. Henson and Jeanne M. Robinson 1994 11 p Presented at the International Symposium on Optoelectronic and Microwave Engineering, Los Angeles, CA, 22-28 Jan. 1994

(Contract W-7405-eng-36)

(DE94-007564; LA-UR-94-606; CONF-940114-3) Avail: CASI HC A03/MF A01

We have applied the technique of second harmonic generation to the study of the solid/vapor interface of porous toluene/water ice films at low temperature. The ice samples are condensed from the vapor onto a cold support at 90 K and are typically approximately 500 microns thick with an internal surface area of approximately 200 m(exp 2). The ices are transparent to both the 532 nm probe laser and to the 266 nm second harmonic signal. Second harmonic light is generated from surfaces throughout the bulk of the porous sample. Significant differences in the efficiency for second harmonic generation from water and toluene enable the species specific study of annealing and adsorption in this binary system. Measurements of the coverage dependent adsorption of toluene on water ice, and the observation of a coverage dependent liquid-solid phase transition in a few monolayers of toluene adsorbed on water ice at temperatures below the bulk toluene melting temperature are presented. METHYL CHLORIDE BY WAY OF OXYHYDROCHLORINATION OF METHANE

Nov. 1993 47 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC22-91PC-91030)

(DE94-009129; DOE/PC-91030/T7) Avail: Issuing Activity (Department of Energy (DOE))

The purpose of this contract is to develop a process for converting light alkane gases to methyl chloride via oxyhydrochlorination using highly selective, stable catalysts in fixed-bed reactors designed to remove the large amount of heat generated, so as to control the reaction temperature. Further, the objective is to obtain the engineering data base necessary for developing a commercially feasible process and to evaluate the economics of the process. This document reports significant progress this quarter toward the development of a stable heterogeneous packed bed catalyst for the oxyhydrochlorination of methane. This quarter's data shows a catalyst which gave an average 18% methane conversion and 78% MeCl selectivity for a 12 day period of time. The PDU (process development unit) design engineering effort made significant progress this quarter. A bid on a modular unit by Xytel Corporation was received and evaluated. The pre-engineering estimate showed that costs were considerably higher than the original project capital estimates. A rigorous effort was made to eliminate all nonessential equipment and scope of work. A reduced scope was agreed upon and in the second round both Xytel and the Dow Corning in-house facilities engineering team were allowed to bid on the package. DOE

TIME-RESOLVED ANALYTICAL METHODS FOR LIQUID/SOLID INTERFACES

J. M. Harris 15 Nov. 1993 8 p

(Contract DE-FG03-93ER-14333)

(DE94-008352; DOE/ER-14333/1) Avail: CASI HC A02/MF A01

Chemical phenomena occurring at boundaries between insulating solids and liquids (adsorption, partition, monolayer self-assembly, catalysis, and chemical reactions) are important to energy-related analytical chemistry. These phenomena are central to chromatography, solid-phase extraction, immobilized analytical reagents, and optical sensors. Chemical interactions in these processes cannot generally be identified solely by equilibrium surface concentrations, since the steady-state behavior does not reveal the mechanism or rates of surface reactions. Therefore, the goal is to develop surface-sensitive spectroscopies by which chemical kinetics at liquid/solid interfaces can be observed on time-scales from nanoseconds to seconds. In the first year, we have used Joule-discharge heating kinetics to study pore structure of silica gels; effects of pore diameter, particle size, and chemical modification on pore connectivity were investigated. Temperature-jump relaxation measurements of sorption/desorption kinetics at liquid/solid interfaces were also carried out using Joule heating; kinetic barriers to sorption of ions from solution were found for both C-18 and Cl surfaces. Through a collaboration with Fritz-Haber Institute in Berlin, we were able to acquire laser temperature-jump data on kinetics at liquid/solid interfaces using a colloidal sample. We also quantified the rate of migration of covalently attached ligands on silica surfaces; from the temperature

dependence, the large energy barrier to migration was estimated. A review of applications of electronic spectroscopy (absorption and fluorescence) to reversed-phase chromatographic interfaces was published. DOE

PRECONDITIONED TIME-DIFFERENCE METHODS FOR ADVECTION-DIFFUSION-REACTION EQUATIONS
C. Aro, G. Rodrigue, and D. Wolitzer Jan. 1994 4 p Presented at the Colorado Conference on Iterative Methods, Breckenridge, CO, 4-10 Apr. 1994
(Contract W-7405-eng-48)
(DE94-006472; UCRL-JC-115840; CONF-9404103-1) Avail: CASI HC A01/MF A01

Explicit time differencing methods for solving differential equations are advantageous in that they are easy to implement on a computer and are intrinsically very parallel. The disadvantage of explicit methods is the severe restrictions placed on step size due to stability. Stability bounds for explicit time differencing methods on advection - diffusion - reaction problems are generally quite severe and implicit methods are used instead. The linear systems arising from these implicit methods are large and sparse so that iterative methods must be used to solve them. In this paper we develop a methodology for increasing the stability bounds of standard explicit finite differencing methods by combining explicit methods, implicit methods, and iterative methods in a novel way to generate new time-difference schemes, called preconditioned time-difference methods. IGNITION DELAYS, HEATS OF COMBUSTION, AND REACTION RATES OF ALUMINUM ALKYL DERIVATIVES USED AS IGNITION AND COMBUSTION ENHANCERS FOR SUPERSONIC COMBUSTION Final Report
Thomas W. Ryan, III, S. T. Schwab, and W. W. Harlowe Feb. 1992 20 p
(Contract NAS1-18191; SwRI Proj. 01-1302; RTOP 505-62-40-01)
(NASA-CR-189581; NAS 1.26:189581) Avail: CASI HC A03/MF A01

The subject of this paper is the design of supersonic combustors which will be required in order to achieve the needed reaction rates in a reasonable sized combustor. A fuel additive approach, which is the focus of this research, is the use of pyrophorics to shorten the ignition delay time and to increase the energy density of the fuel. Pyrophoric organometallic compounds may also provide an ignition source and flame stabilization mechanism within the combustor, thus permitting use of hydrocarbon fuels in supersonic combustion systems. Triethylaluminum (TEA) and trimethylaluminum (TMA) were suggested for this application due to their high energy density and reactivity. The objective here is to provide comparative data for the ignition quality, the energy content, and the reaction rates of several different adducts of both TEA and TMA. The results of the experiments indicate the aluminum alkyls and their more stable derivatives reduce the ignition delay and total reaction time to JP-10 jet fuel. Furthermore, the temperature dependence of ignition delay and total reaction time of the blends of the adducts are significantly lower than in neat JP-10. Author (revised)

THE DEVELOPMENT OF PRECIPITATED IRON CATALYSTS WITH IMPROVED STABILITY
H. Abrevaya 27 Dec. 1993 278 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC22-87PC-79812)
(DE94-008711; DOE/PC-79812/T17) Avail: CASI HC A13

Precipitated iron catalysts are expected to be used in next generation slurry reactors for large-scale production of transportation fuels from synthesis gas. These reactors are expected to operate at higher temperatures and lower H2:CO ratios relative to the Sasol Arge reactor. The feasibility of using iron catalysts has been demonstrated under relatively mild Arge-type conditions but not under more severe slurry conditions. Possibly, an improvement in catalytic stability will be needed to make iron catalysts suitable for slurry operation. This program was aimed at identifying the chemical principles governing the deactivation of precipitated iron catalysts during Fischer-Tropsch synthesis and use of these chemical principles in the design of more stable catalysts. A new precipitated Fe catalyst was developed in this program for slurry reactor operation. The new Fe catalyst is predicted to perform slightly below the performance targets for slurry bubble column operation. Stability targets appear to be achievable. This catalyst did not noticeably deactivate during 1,740 hours on-stream. Compared to the selectivity target, an excess of 2 percent C1 + C2 was formed at 265 C. Based on the initial catalyst inventory in the autoclave, the catalyst seems to be short of the activity target by a factor of 1.8 at 265 C and 1.3 at 275 C. However, actual specific activities are likely to be closer to target because of catalyst inventory loss across the filter during the run and because catalytic activities were underestimated at low conversions. The pyrolysis of methane in the absence of a quench was studied at temperatures between 900 and 1050 C and methane flows of 80 to 200 Scc/minute. At 1050 C and a methane flow rate of 100 Scc/minute, methane conversion ranged between 15 and 19 percent with the major products being benzene, acetylene, and ethylene. The benzene molar selectivity was approximately 50 percent, corresponding to molar yield of approximately 7.5 to 10 percent. The reaction resulted in the formation of visible amounts of solid carbon, particularly at 1050 C. The resulting solid consisted partly of carbon and partly of a yellowish tar-like material which was soluble in toluene and contained various heavy hydrocarbons and polyring aromatics. DOE

TECHNOLOGY DEVELOPMENT FOR IRON FISCHER-TROPSCH CATALYSTS
B. H. Davis 1993 36 p
(Contract DE-AC22-91PC-90056)
(DE94-008723; DOE/PC-90056/T13) Avail: CASI HC A03/MF A01

Slurry phase Fischer-Tropsch synthesis was conducted with an ultrafine iron oxide catalyst promoted with either K or Zr or both. Pretreatment in CO yielded higher conversions and a more stable catalyst than activation in hydrogen or synthesis gas. Hydrogen pretreatment of K promoted catalysts and synthesis gas activation in general were less effective. Mossbauer spectroscopy and XRD showed X-Fe5C2 and (epsilon)-Fe(2.2)C were formed during pretreatment in CO and did not depend on promoters present. Catalysts pretreated in H2 were reduced to metallic Fe and Fe3O4; promotion with K and Zr decreased the extent of reduction. Hydrogen pretreated catalysts with K lost surface area and carbided rapidly under synthesis conditions. Activation in synthesis gas reduced all catalysts to Fe3O4. Subsequent synthesis did not effect the phase present for the unpromoted and Zr promoted catalysts while those with K formed X-Fe5C2 and (epsilon)-Fe(2.2)C. It is concluded that pretreatment type is more important to the catalyst activity during the early period of synthesis than the impact of promotion with K and Zr. DOE

The NASA Lewis chemical equilibrium program with applications continues to be improved and updated. The latest version is CET93. This code, with smaller arrays, has been compiled for use on an IBM or IBM-compatible personal computer and is called CETPC. This report is intended to be primarily a users manual for CET93 and CETPC. It does not repeat the more complete documentation of earlier reports on the equilibrium program. Most of the discussion covers input and output files, two new options (ONLY and comments), example problems, and implementation of CETPC. Author

DIELECTRIC VISCOMETER INCLUDING FIXED AND VARIABLE CELLS Patent
John G. Williams, inventor (to Navy), Thomas M. Donnellan, inventor (to Navy), and Ronald E. Trabocco, inventor (to Navy) 18 Jan. 1994 7 p Filed 22 Jun. 1992
(AD-D016139; US-Patent-5,279,149; US-Patent-Appl-SN-902138; US-Patent-Class-73-54.01) Avail: US Patent and Trademark Office

A parallel plate dielectric viscometer is provided for measuring the viscosity of a substance having differing substance dielectric properties at differing substance viscosities. Two electrodes are disposed in opposition to each other forming a variable dielectric cell having a dielectric distance between the electrodes. The viscosity of the substance is varied and force is applied to the substance to vary the dielectric distance according to the varying viscosity. The rate of change of the dielectric distance with respect to time is used to determine the viscosity of the substance. The viscosity may be varied by heating the substance and force may be applied to the substance by way of one of the electrodes such that the dielectric distance between the electrodes decreases as the substance becomes more viscous. A fixed cell may also be provided in order to correct for the effects of chemical changes in the substance. DTIC

COMPUTED POTENTIAL ENERGY SURFACES FOR CHEMICAL REACTIONS Final Technical Report, 1 Jul. 1987 - 31 Jan. 1994
Stephen P. Walch 9 May 1994 11 p
(Contract NCC2-478)
(NASA-CR-195835; NAS 1.26:195835) Avail: CASI HC A03/MF A01

Quantum mechanical methods have been used to compute potential energy surfaces for chemical reactions. The reactions studied were among those believed to be important to the NASP and HSR programs and included the recombination of two H atoms with several different third bodies; the reactions in the thermal Zeldovich mechanism; the reactions of H atom with O2, N2, and NO; reactions involved in the thermal De-NO(x) process; and the reaction of CH(squared Pi) with N2 (leading to 'prompt NO'). These potential energy surfaces have been used to compute reaction rate constants and rates of unimolecular decomposition. An additional application was the calculation of transport properties of gases using a semiclassical approximation (and in the case of interactions involving hydrogen inclusion of quantum mechanical effects). An experimental and computational investigation of supersonic combustion flows has been carried out. The principal objective of the research was to gain a more fundamental understanding of mixing and chemical reaction in supersonic flows. The research effort comprised three inter-related elements: (1) an experimental study of mixing and combustion in a supersonic plane mixing layer; (2) development of laser-induced fluorescence techniques for time-resolved multidimensional imaging of species concentration, temperature, velocity and pressure; and, (3) analyses and numerical simulations of compressible reacting flows. The specific objectives and results of the research of each of these program elements are summarized in this report. DTIC

ENHANCED THERMAL CAPACITY AEROGELS SUMMARY REPORT, FY 1993
L. W. Hrubesh, P. R. Coronado, and J. F. Poco Dec. 1993 13 p
(Contract W-7405-eng-48)
(DE94-008888; UCRL-CR-115799-Summ) Avail: CASI HC A03/MF A01

In a continuation of work done previously, the authors have fabricated a set of silica aerogels and then chemically modified their internal surfaces for the purpose of inhibiting the effects of sintering at high temperatures. They performed surface nitridation of silica aerogels, i.e., the replacement of surface oxygen atoms with nitrogen atoms, by reacting ammonia gas with the silica surfaces at elevated temperatures. After pre-oxidizing the aerogels, they exposed three sets of samples to anhydrous ammonia gas under different processing conditions. Each set contained silica aerogels of three different densities: 0.07 g/cc, 0.16 g/cc, and 0.29 g/cc. The treated samples, together with companion untreated reference samples, were sent to NASA Ames Research Laboratory for high temperature testing. They also fabricated two carbon aerogel cylinders: 7 cm diameter x 1.5 cm thick. These samples were also delivered to NASA Ames Research Laboratory for high temperature tests. DOE

ENHANCEMENT OF OXIDATION RESISTANCE OF SILICON CARBIDE BY HIGH-DOSE AND MULTI-ENERGY ALUMINUM IMPLANTATION
Z. Yang (Stevens Inst. of Tech., Hoboken, NJ.), H. Du (Stevens Inst. of Tech., Hoboken, NJ.), M. Libera (Stevens Inst. of Tech., Hoboken, NJ.), S. P. Withrow, L. M. Casas, and R. T. Lareau 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-006560; CONF-931108-70) Avail: CASI HC A02/MF A01

High-dose and multi-energy aluminum implantation of alpha-SiC (0001) was carried out to achieve a broad aluminum distribution extending from the sample surface to a depth of approximately 350 nm. Oxidation resistance of the implanted crystals was studied in 1 atm flowing oxygen at 1300C. Aluminum implantation resulted in a 45% improvement in the oxidation resistance of alpha-SiC as compared with unimplanted crystals due to the formation of structurally dense mullite (3Al(2)O(3).2SiO(2)) in the oxidation scale. (DE94-007450; DOE/ER-45287/6) Avail: CASI HC A03/MF A01

This section summarizes the progress made in this program since the its renewal on June 1, 1992 to date. This program is seeking to characterize the cause of embrittlement that results when certain solid metals and their alloys are exposed to other metals, usually, but not necessarily, in liquid form. The research is examining a number of factors that influence the degree of embrittlement and is also attempting to develop the basis for understanding, the underlying cause of embrittlement. Accordingly, the program involves both theoretical and experimental approaches. DOE

HIGH TEMPERATURE DUCTILITY LOSS IN TITANIUM ALLOYS: A REVIEW
B. B. Rath, M. A. Imam, B. K. Damkroger, and G. R. Edwards 1994 16 p Presented at the 1994 TMS Annual Meeting on Actinides, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006606; SAND-94-0283C; CONF-940221-3) Avail: CASI HC A03/MF A01

It is well known that two phase titanium alloy systems suffer from an abrupt drop in ductility at elevated temperatures in the range of 1,000 to 1,150 K. This loss of ductility is manifested by easy decohesion of polycrystalline aggregates along the grain boundaries of the high temperature beta phase. If the alloy is in a state of tensile stress at the aforementioned temperatures, cracks initiate at the grain boundaries and propagate readily through the alloy, leading to premature failure. This phenomenon is a cause of major concern in titanium alloy fabrication and welding. Several mechanisms have been proposed to explain high temperature crack nucleation and growth along the boundaries. A critical review of the phenomenon and possible mechanisms responsible for the observed behavior will be discussed. DOE

Two routes of ductilization of the Al3Ti-DO22 compound are explored: the development of Ll2Al3Ti based alloys with ternary additions (Cr, Mn, Cu); and the use of the nonequilibrium melt spinning process, in order to produce a fine dispersion of an Al3Ti based phase in an Al matrix. The alloys are fully characterized using X-ray diffraction and both scanning and transmission electron microscopy. Differential scanning calorimetry and microhardness tests are used to assess the thermal stability of the structures. Ll2 single phase field is identified in the ternary systems Al-Ti-M (M = Cr, Mn, Cu) but its extent varies strongly with both temperature and composition. The existence of a two phase Ll2-Al2Ti field is demonstrated in the Al-Ti-Cu system. Moreover, several antiphase modulations are identified under high resolution microscopy. Melt spun ribbons exhibit locally a two phase Al-Ll2 structure in the Al-Ti-Cu and Al-Ti-Fe systems and a two phase Al-DO22 structure in the Al-Ti-Mo system. The production of alloy rods by hot extrusion is restricted to a volume fraction smaller than 50 percent of the intermetallic phase. Compression tests reveal that the two phase alloys are considerably more resistant than the single phase at room temperature. This behavior is attributed to a strong effect of modulus between the matrix and the intermetallic phase. Dynamic strain ageing and plastic instabilities are observed at 300 C in both the two phase and single phase alloys. ESA

TRANSMISSIBILITY OF NICKEL-TITANIUM SHAPE MEMORY ALLOY SPRINGS Technical Report, Oct. 1992 - Apr. 1993
Edward J. Graesser Dec. 1993 26 p
(AD-A276055; CarderockDiv-MRD-93/25) Avail: CASI HC A03/MF A01

A research study was undertaken to measure the transmissibility of nickel-titanium (Ni-Ti) shape memory alloy (SMA) springs and compare the results to corresponding data on steel and Inconel springs. It was motivated by interest in an effective metal alternative to rubber-based machinery isolation mounts, with possible active control features. Ni-Ti was used due to its well known properties of shape memory and high intrinsic damping. Acceleration transmissibility was measured on a spring-mass system. Due to the distributed mass in the spring coils, standing waves occurred at high frequencies. However, due to the high intrinsic damping in Ni-Ti, the standing wave resonance peaks were as much as 20 db lower than corresponding peaks in steel and Inconel springs. Thus the capability of

Ni-Ti springs for high frequency vibration isolation is significantly better than that of steel or Inconel. Also, it is judged that the Ni-Ti material could be used in a variety of other isolation mount designs with a high likelihood for further improvement in passive isolation properties. In addition, it may be possible to use the shape memory effect in active control concepts. DTIC

CREEP PROPERTIES OF VANADIUM-BASE ALLOYS
H. M. Chung, B. A. Loomis, and D. L. Smith Dec. 1993 10 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-006541; ANL/ET/CP-81785; CONF-930928-27) Avail: CASI HC A02/MF A01

Vanadium-base alloys are promising candidate materials for application in fusion reactor structural components because of several important advantages. V-4Cr-4Ti has been identified as one of the most promising candidate alloys and was selected for comprehensive tests and examination. In the present investigation, thermal creep rates and stress-rupture life of V-4Cr-4Ti and V-10Cr-5Ti alloys were determined at 600 C. The impurity composition and microstructural characteristics of creep-tested specimens were analyzed and correlated with measured creep. Results show that V-4Cr-4Ti, which contains impurity compositions typical of a commercially fabricated vanadium-based alloy, exhibits creep strength substantially superior to that of V-20Ti, HT-9, or Type 316 stainless steel. The V-10Cr-5Ti alloy exhibits creep strength somewhat higher than that of V-4Cr-4Ti. DOE

CHEMICAL VAPOUR DEPOSITION OF TUNGSTEN FOR THE APPLICATION IN INTEGRATED CIRCUITS Ph.D. Thesis
Albert Hasper 1992 148 p Sponsored by Dutch Innovative Research Program
(ISBN-9-09-005151-1; ETN-94-96026) Copyright Avail: CASI HC A07/MF A02

The results of research aimed at the implementation of tungsten in a BiCMOS (Bipolar and CMOS) process is described. The growth of tungsten by the reactions of WF6 with H2, SiH4, and Si was studied with emphasis on reactor technology and device aspects. The cold wall reactor used for tungsten deposition is a nonisothermal system, and thus, large temperature differences occur between wafer and the heating hot plate, especially at the typical low pressures for LPCVD (Low Pressure Chemical Vapor Deposition). The problem of wafer temperature behavior in cold wall systems is described. A model that predicts the wafer temperature in such systems as a function of total pressure, gas composition, and coatings of wafer susceptor, is formulated. Experimentally found growth rates are compared with the growth rates predicted by a mathematical reactor simulation model. The combination of the mathematical reactor model and a step coverage model is described, measurement and analysis of selectively filled tungsten contacts are addressed, and the application of W-LPCVD on a BiCMOS process is described. TENSILE PROPERTIES OF COMMERCIALLY PURE VANADIUM FROM ROOM TEMPERATURE TO 1200 C
G. A. Henshall and S. G. Torres Dec. 1993 34 p
(Contract W-7405-eng-48)
(DE94-006622; UCRL-ID-114591) Avail: CASI HC A03/MF A01

The tensile properties of vanadium are sensitive to interstitial impurity content and, to some extent, on grain size and strain rate. Thus, it is problematic to use published tensile data for materials potentially varying in these quantities. This investigation was undertaken to fully characterize the tensile properties of the commercially pure vanadium used at Lawrence Livermore. Both sheet and rod stock were tested in vacuum from ambient temperature to 1200 C at strain rates 6.67 x 10(exp -5) to 6.67 x 10(exp -2) s(exp -1). The results of these experiments show that vanadium behaves in a manner typical of many bcc metals containing interstitial impurities. Local peaks in yield stress and ultimate tensile stress versus temperature curves are observed at intermediate temperatures. Serrated yielding also is observed in some temperature ranges. Changes in strain rate within the quasistatic regime have a relatively small, predictable effect. The rod and sheet stock have similar properties, except that the lower yield stress of the rod is less than that of the sheet over most of the temperature range studied. No plateau in yield strength versus temperature curve was observed for the rod. In both forms, and for all temperatures, vanadium is ductile. The elongation to failure reaches a minimum of approximately 35 percent at a temperature of 500 C and a maximum of approximately 140 percent at 1200 C. DOE

(Contract DE-AC06-76RL-01830)
(DE94-006213; PNL-SA-22452; CONF-930928-25) Avail: CASI HC A03/MF A01

A comparison of the predicted and measured electrical conductivities of MARZ copper and two copper alloys irradiated in the Fast Flux Test Facility (FFTF) shows that the calculated transmutation rates agree within 15% with those required to produce the observed changes. It also appears that the contribution of transmutants and void swelling to conductivity changes are directly additive. Of the three models studied, Euken's model has been found to best describe the contribution of void swelling to conductivity loss. DOE

DEFECT-SOLUTE INTERACTIONS NEAR IRRADIATION GRAIN BOUNDARIES
E. P. Simonen, J. S. Vetrano, H. L. Heinisch, and S. M. Bruemmer Nov. 1993 8 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC06-76RL-01830)
(DE94-006215; PNL-SA-22766; CONF-931108-61) Avail: CASI HC A02/MF A01

Defect-solute interactions control radiation-induced segregation (RIS) to interfacial sinks, such as grain boundaries, in metallic materials. The best studied system in this regard has been austenitic stainless steels. Measurements of grain boundary composition indicate that RIS of major alloying elements are in reasonable agreement with inverse-Kirkendall predictions. The steep and narrow composition profiles are shown to result from limited back diffusion near the boundary. Subsequently, defect-solute interactions that affect the near boundary defect concentrations strongly affect RIS. The variability in measured RIS may in part be caused by grain boundary characteristics. DOE

AGING EFFECTS ON THE MICROSTRUCTURE, SURFACE CHARACTERISTICS AND WETTABILITY OF Cu PRETINNED WITH Sn-Pb SOLDERS Ph.D. Thesis
H. S. Linch Nov. 1993 73 p
(Contract DE-AC03-76SF-00098)
(DE94-007033; LBL-34991) Avail: CASI HC A04/MF A01

This study investigates effects of aging in air and argon at 170 C on Cu coupons which were pretinned with 75Sn-25Pb, 8Sn-92Pb, and 5Sn-95Pb solders. Coatings were applied using electroplating or hot dipping techniques. The coating thickness was controlled between 3 to 30 microns and the specimens were aged for 0 hours, 2 hours, 24 hours, and 2 weeks. Wetting balance tests were used to evaluate the wettability of the test specimens. Microstructural development was evaluated using x ray diffraction, energy dispersive x ray and Auger spectroscopy, and optical and scanning electron microscopy. The wetting behavior of the test specimens is interpreted with respect to observed microstructural changes and as a function of aging time, solder composition, and processing conditions. DOE

EFFECT OF IRRADIATION DAMAGE AND HELIUM ON THE SWELLING AND STRUCTURE OF VANADIUM-BASE ALLOYS
H. M. Chung, B. A. Loomis, and D. L. Smith Dec. 1993 15 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa,

Italy, 27 Sep. - 1 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-006540; ANL/ET/CP-81786; CONF-930928-26) Avail: CASI HC A03/MF A01

Swelling behavior and microstructural evolution of V-Ti, V-Cr-Ti, and V-Ti-Si alloys were investigated after irradiation at 420 to 600 C up to 114 dpa. The alloys exhibited swelling maxima between 30 and 80 dpa and swelling decreased on irradiation to higher dpa. This is in contrast to the monotonically increasing swelling of binary alloys that contain Fe, Ni, Cr, Mo, W, and Si. Precipitation of dense Ti5Si3 promotes good resistance to swelling of the Ti-containing alloys and it was concluded that Ti of greater than 3 wt. percent and 400 to 1000 wppm Si are necessary to effectively suppress swelling. Swelling was minimal in V-4Cr-4Ti, identified as the most promising alloy based on good mechanical properties and superior resistance to irradiation embrittlement. V-20Ti doped with B exhibited somewhat higher swelling because of He generation. Lithium atoms, generated from transmutation of B-10, formed gamma-LiV2O5 precipitates and did not seem to produce undesirable effects on mechanical properties. DOE

ACOUSTIC EMISSION FROM CRACK GROWTH IN 7050 ALUMINUM AND 7075 ALUMINUM AS A FUNCTION OF TEMPERATURE AND HEAT TREATMENT
S. L. McBride and Y. Hong Feb. 1993 14 p
(DREP-CRS-93-15; DSIS-94-01128; CTN-94-61218) Avail: CASI HC A03/MF A01

The acoustic emission behavior of aluminum alloys 7050 and 7075 was investigated under various conditions of temperature and heat treatment. The two alloys are chemically and mechanically very similar apart from the presence of Mg2Si inclusions in the 7075 aluminum. During fatigue crack propagation, the amplitude of each acoustic emission signal was recorded for analysis along with the specimen load, number of load cycles, time, and crack length at which the signal occurred. It is shown that the crack propagation acoustic emission behavior is quite different for the two alloys. For similar heat treatment and temperature conditions, the number and amplitude of the acoustic emission events in 7050 and 7075 aluminum decreases with increasing temperature and with increasing overaging time. The measured amplitudes of the acoustic emission signals are linearly related to the source energy. For 7050 aluminum, the acoustic emission source energy is a fixed fraction of the strain energy release rate for fatigue crack advance. This fraction is a function of heat treatment and ambient crack growth temperature. For 7075 aluminum the acoustic emission source energy is independent of the strain energy release rate. This behavior may be due to the effect of Mg2Si inclusions within the process zone.

CREEP-FATIGUE CRITERIA AND INELASTIC BEHAVIOR OF MODIFIED 9Cr-1Mo STEEL AT ELEVATED TEMPERATURES
M. B. Ruggles and T. Ogata Feb. 1994 60 p Prepared for Electric Power Research Inst., Palo Alto, CA
(Contract DE-AC05-84OR-21400)
(DE94-007915; ORNL/M-3198) Avail: CASI HC A04/MF A01

The ever increasing demand for safety requires that stringent and conservative methodology be developed for design and analysis of reactor components. At present modified 9Cr-1Mo steel is a candidate material for construction of steam generators in fast breeder reactors. Therefore high-temperature material properties and extensive insight into deformation behavior and creep-fatigue life are required to develop design guidelines for use of modified 9Cr-1Mo steel in actual plant components. However, existing information on creep-fatigue and deformation response of modified 9Cr-1Mo steel is insufficient, and further experimental and modeling efforts are needed. A joint effort between the Electric Power Research Institute (EPRI) in the United States and the Central Research Institute of Electric Power Industry (CRIEPI) in Japan was started in 1991 to investigate the inelastic behavior of and to develop creep-fatigue criteria for modified 9Cr-1Mo steel at elevated temperatures. The current program focuses on uniaxial and biaxial fatigue, creep, and creep-fatigue tests. Results of this effort are presented in this report. Section 2 introduces the test material and experimental arrangement. Uniaxial exploratory deformation tests and unified constitutive equations for inelastic analysis of modified 9Cr-1Mo steel are presented in Sections 3 and 4, respectively. Axial fatigue and creep-fatigue test results are discussed in Section 5. Section 6 is devoted to constant stress creep tests. Biaxial fatigue and creep-fatigue tests are described in Section 7. Progress in creep-fatigue life evaluation is reported in Section 8. DOE

PREDICTION OF HYDROGEN ENTRY AND PERMEATION IN METALS AND ALLOYS Final Report, 1 Oct. 1990 - 30 Sep. 1993
H. W. Pickering 30 Sep. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1189)
(AD-A276637) Avail: CASI HC A03

This Grant focused on the investigation of the factors which affect hydrogen entry and permeation into metals/alloys that by themselves or in combination with other materials are used under conditions for which hydrogen embrittlement and cracking are a major concern. Factors that affect H entry include a broad range of metallurgical, environmental and interface properties such as adsorption, surface segregation, surface films and recesses in the surface. Research during this grant period focused on understanding how these parameters control hydrogen entry. The specific investigations included both aqueous and gas phase charging of hydrogen, utilizing primarily electrochemical techniques, in particular hydrogen permeation with the IPZ model, and microscopic methods in the case of aqueous phase charging, and ultra high resolution scanning tunneling microscopy (STM) in the case of gas phase charging. THE ADSORPTION OF SULFATE ON GOLD(111) IN ACIDIC AQUEOUS MEDIA: ADLAYER STRUCTURAL INFERENCES FROM INFRARED SPECTROSCOPY AND SCANNING TUNNELING MICROSCOPY
Xiao-Ping Gao, Michael J. Weaver, and Gregory J. Edens Feb. 1994 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1409)
(AD-A276643; TR-148) Avail: CASI HC A03

The potential-dependent adsorption of sulfate on ordered Au(111) from acidic aqueous electrolytes has been examined in-situ by means of infrared reflection-absorption spectroscopy (IRAS) and by atomic-resolution scanning microscopy (STM) in order to explore further the nature of the adsorbate bonding and the structural changes attending the formation of the ordered adlayer at high potentials, as observed recently by using STM. Solution conditions that encompassed aqueous sulfuric acid, sulfuric acid/sulfate electrolytes of varying pH, and dilute sulfate in excess perchloric acid were selected in order to facilitate comparisons with recent adsorbate compositional data extracted from chronocoulometric and radiotracer measurements which utilized the last type of electrolyte. Essentially the same ordered adlayer structures were deduced by STM to form at suitably high potentials (greater than 0.8 V vs. SCE) in both sulfuric acid and the mixed sulfate/excess perchloric acid media. The adlayer, which exhibits a (sq. rt.3 x sq. rt.7) symmetry, involves a fractional sulfate coverage of 0.2, in accordance with chronocoulometic and radiotracer data. The possibility that the ordered sulfate adlayer incorporates coadsorbed hydronium cations is discussed; such coadsorption is suggested by the presence of additional tunneling maxima in the STM images. The IRAS data display a prominent S-O stretching band (nu(sub so)) at 1155-1220 cm(exp -1). The appearance of this nu(sub so) feature is also insensitive to the electrolyte conditions, including pH, consistent with its assignment to adsorbed sulfate, rather than to bisulfate. DTIC

Metal thiolates of the general formula M(SR)2 (M = Pb, Zn, Cd) and Cl-Hg-SR (R = alkyl) have been prepared and characterized by spectroscopic techniques, TGA and, in selected cases, single crystal X-ray diffraction. The metal bis(thiolate) compounds can be converted into the related metal sulfides by thermolyses. The solid state materials have been

characterized by XRPD, SEM and, in selected cases, by particle size determination. The volatile pyrolytic co-products have been isolated and characterized by GC/MS. The decomposition pathways of mercury chlorothiolates are more complicated and depend on the nature of the organic group present in Cl-Hg-SR. DTIC

A NEW-TYPE OF LONG-RANGE RESTRUCTURING OF ORDERED METAL SURFACES INDUCED BY LATERAL ADSORBATE INTERACTIONS: IODIDE ON AU(110) ELECTRODES

Xiaoping Gao and Michael J. Weaver Feb. 1994 18 p

(Contract N00014-91-J-1409)

(AD-A276633; TR-150) Avail: CASI HC A03/MF A01

A new form of long-range surface restructuring of Au(110) is reported, specifically for Au(110) in aqueous iodide electrolyte at high electrode potentials where an ordered iodide adlayer is present. In-situ scanning tunneling microscopy reveals the formation of periodic terrace strips paralleling the direction with widths, ca 25-40 A, that diminish as the surface potential is increased. The (1 x 1) substrate unit cell, however, remains unaffected. The restructuring is postulated to be due to dipole-dipole repulsive interactions destabilizing terrace sites distant from steps, and hence limiting the size of the substrate-adlayer domains. DTIC

WORK HARDENING BEHAVIOR IN ALUMINUM ALLOY 2090 Ph.D. Thesis

C. Tseng Dec. 1993 64 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC03-76SF-00098)

(DE94-007036; LBL-35057) Avail: Issuing Activity (Department of Energy (DOE))

An investigation into the work hardening behavior of an aluminum alloy 2090-T81 Al-3.05Cu-2.16Li-0.12Zr at various test temperatures, heat treatment conditions and microstructures was conducted. One microstructure consisted of unrecrystallized, highly textured grains, and the other microstructure was composed of recrystallized grains. Microstructural effects on work hardening were divided into two levels of contribution: the grain structure level, which consisted of the grain size and shape, subgrains and texture, and the microconsistent level, which included the precipitates and solutes. Two heat treatments were studied: the as-received, peak-aged condition, and the solution heat treated condition where the as-received plate was re-solutionized. Observations of the deformed surface of both as-received grain structures at various prestrains indicated that there was no correlation between an increase in slip homogeneity and an increase in work hardening. The increase in out-of-plane grain rotation at lower temperatures was not primarily responsible for the increase in work hardening. In addition, the fully plastic deformation microstructure for the unrecrystallized microstructure appeared very inhomogeneous as the grains deformed in bands; there were also bands of grains that had very little to no deformation. From the work hardening plots it was found that an unrecrystallized, (110)/112/ textured grain structure with a homogeneous distribution of subgrains produced the highest rate of work hardening between 300 K and 77 K. When the microconstituents are added to both grain structures, both the work hardening rate in the elastic-plastic and fully plastic regimes and the level of work hardening at which the elastic-plastic to fully plastic transition occurred were affected. METAL CLUSTERS: DYNAMICS AND STRUCTURE Final Report, 15 Dec. 1991 - 14 Dec. 1993

Emily A. Carter 14 Dec. 1993 14 p

(Contract N00014-89-J-1492)

(AD-A276842) Avail: CASI HC A03/MF A01

During the tenure of this grant, we have examined the dynamics and structure of metal clusters in the gas phase and on surfaces. We have extended the concept of cluster to also examine metallic interactions in two-dimensional islands and thin films. We have used both quantum mechanical approaches and classical Monte Carlo/Molecular Dynamics simulations. In addition, we have continued our development of a new first principles dynamics scheme specifically designed with atomic clusters in mind. The projects we have completed include: (1) the electronic structure and metal-metal bonding in low-lying states of Pt2 and Pt3; (2) structure and growth mechanisms of Pd two-dimensional clusters (islands) on bcc(110) substrates as a function of coverage; (3) structure, growth, and interdiffusion of Ni films on Ag(100); and (4) development of a systematic guide to choosing the size and shape of a simulation cell using periodic boundary conditions for use in studying interfaces between crystalline solids of different density and symmetry. THE NEW METALS AND ALLOYS INDEXES, SEARCH MANUAL: A PHASE DIAGRAM RESEARCH TOOL

M. H. Mueller, P. L. Wallace, T. C. Huang, and J. N. Dann 1993 12 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993

(Contract W-31-109-eng-38)

(DE94-005371; ANL/FE/CP-81703; CONF-931009-19) Avail: CASI HC A03/MF A01

A new Metals and Alloys (M&A) Indexes to the powder diffraction file (PDF) has been developed. These indexes will be immediately useful to material scientists because the indexes share many features with references such as Hansen, Elliot, Shunk, Pearson, and Villars and Calvert. These indexes, as contained in the search manual, may be used independently or in conjunction with the powder diffraction file. The book contains four indexes: two contain data for all materials in the M&A PDF and two contain supporting data. The permuted-sort Alphabetical Formula Index brings together all entries containing a given element in alphabetical formula order. It has n entries for an n-component material and a straight-line format for the element being sorted to simplify reading the index. Thus, chemical knowledge can make identifications easier. Further, within binary and ternary phase diagrams, phases are listed in compositional order to facilitate direct use in phase diagram research. The Pearson Symbol Code Index has entries arranged in order of the Pearson symbol code, hence one can find all the materials with a given structure and, if desired, compare their atomic contents and lattice parameters. The latter are in the standard crystal data setting to aid in structural comparisons. The Common Names Index cross-references common metallurgical names, such as austenite or cementite, to the appropriate PDF data. The Strukturbericht Symbol Index cross-references Strukturbericht symbols and the equivalent Pearson symbols and structure prototypes. Examples of the uses of this index in phase diagram research are given. DOE

IRRADIATION-ASSISTED STRESS CORROSION CRACKING OF MATERIALS FROM COMMERCIAL BWRs: ROLE OF GRAIN-BOUNDARY MICROCHEMISTRY

H. M. Chung, W. E. Ruther, J. E. Sanecki, A. G. Hins, and T. F. Kassner Dec. 1993 18 p Presented at the Water Reactor Safety Information Meeting, Bethesda, MD, 25-27 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-31-109-eng-38)

(DE94-006542; ANL/ET/CP-80141; CONF-931079-17) Avail: CASI HC A03

Constant-extension-rate tensile tests and grain-boundary analysis by Auger electron spectroscopy were conducted on high- and commercial-purity (HP and CP) Type 304 stainless steel (SS) specimens. The specimens were from irradiated boiling-water reactor (BWR) components. The tests were performed to determine susceptibility to irradiation-assisted stress

corrosion cracking (IASCC) and to identify the mechanisms of intergranular failure. The susceptibility of HP neutron absorber tubes to intergranular stress corrosion cracking (IGSCC) was higher than that of CP absorber tubes or CP control blade sheath. Contrary to previous beliefs, susceptibility to intergranular fracture could not be correlated with radiation-induced segregation of impurities such as Si, P, C, N, or S, but a correlation was obtained with grain-boundary Cr concentration. This indicated a role for Cr depletion that promotes IASCC. Detailed analysis of grain-boundary chemistry was conducted on neutron absorber tubes that were fabricated from two similar heats of HP Type 304 SS of virtually identical bulk chemical composition but exhibiting a significant difference in susceptibility to IGSCC for similar fluence. Grain-boundary concentrations of Cr, Ni, Si, P, S, and C in the crack-resistant and susceptible HP heats were virtually identical. However, grain boundaries of the cracking-resistant material contained less N and more B and Li (transmutation product from B) than those of the crack-susceptible material indicating beneficial effects of low N and high B contents. DOE

VIBRATIONAL SPECTROSCOPY AT METAL-SOLUTION INTERFACES: SOME PERSPECTIVES AND PROSPECTS FOR ELECTROCHEMICAL SURFACE SCIENCE
Michael J. Weaver, N. Kizhakevariam, X. Jiang, I. Villegas, and C. Stuhlmann Feb. 1994 13 p
(Contract N00014-91-J-1409)
(AD-A276781; TR-143) Avail: CASI HC A03/MF A01

Some recent applications of surface vibrational spectroscopies to electrochemical and related interfacial systems are illustrated by means of studies undertaken in the authors' laboratory. The utility of infrared reflection-absorption spectroscopy (IRAS) for linking the structural behavior of absorbates on ordered metal surfaces in electrochemical and vacuum environments is discussed with reference to a vacuum-based study of CO/D2O coadsorption on Pt(111). The use of atomic-resolution scanning tunneling microscopy in tandem with in-situ IRAS for electrochemical adlayer structural elucidation is noted. Some virtues of surface-enhanced Raman spectroscopy (SERS) for examining metal-adsorbate vibrations on transition metals in both electrochemical and high-pressure gas-phase systems are also briefly illustrated, specifically for rhodium surface oxidation.

FATIGUE TESTING OF 2024-T3 MATERIAL AFTER FOUR CYCLES OF PMB STRIPPING Final Report
Nov. 1993 58 p
(Contract DTFA03-89-C-00043)
(AD-A276926; DOT/FAA/CT-93/43) Avail: CASI HC A04/MF A01

The goal of this program was to determine the effect of plastic media blasting (PMB), an alternative to chemical paint removal, on the fatigue life of 2024-T3 aluminum. Two surface treatments, anodized and alclad, of three thicknesses: 0.032 inch, 0.040 inch, and 0.050 inch were considered. A number of alclad and anodized aluminum panels of the alloy and thicknesses specified were subjected to four cycles of PMB. The blast parameters were identical to those used in a previous FAA program. Almen strips tests were performed to quantify the blast intensity. A fatigue testing program was conducted on both the 'as received' and the PMB treated material. Reductions in mean fatigue life were observed for all materials tested after PMB treatment. These reductions were statistically significant for the 0.032 alclad and 0.040 anodized specimens. DTIC

CONTINUOUS MEASUREMENT OF AGING RESPONSE IN ALUMINUM ALLOYS BY EDDY CURRENT METHODS M.S. Thesis
Silvester G. Mata Dec. 1993 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277233) Avail: CASI HC A04

The objective of this research was to further investigate the use of a sensor system to continuously monitor the aging response of heat treatable aluminum alloys. This concept of continuous monitoring is referred to as Intelligent Processing. The bridge consists of eddy current coils incorporated in an impedance bridge circuit, with modifications following earlier work by Esarey. The system continuously monitors a material property, resistivity, indicative of the aging process. The results of such continuous measurements, combined with mechanical test data, will allow one to gain active control of the aging process and hence the material properties of aluminum alloys. The ultimate results would be higher reliability of engineering structures. The increased precision in control of heat treatment processes would allow more narrow performance and greater service life of engineering structures. DTIC

RECENT ADVANCES AND DEVELOPMENTS IN REFRACTORY ALLOYS
T. G. Nieh and J. Wadsworth Nov. 1993 13 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-48)
(DE94-007929; UCRL-JC-116117; CONF-931108-90) Avail: CASI HC A03/MF A01

Refractory metal alloys based on Mo, W, Re, Ta, and Nb (Cb) find applications in a wide range of aerospace applications because of their high melting points and high-temperature strength. This paper presents recent progress in the understanding and applications of these alloys. Recent studies to improve the oxidation and mechanical behavior of refractory metal alloys, and particularly Nb alloys, are also discussed. Some Re structures, for extremely high temperature applications (greater than 2000 C), made by CVD and P/M processes, are also illustrated. Interesting work on the development of new W alloys (W-HfC-X) and the characterization of some commercial refractory metals, e.g., K-doped W, TZM, and Nb-1%Zr, continues. Finally, recent developments in high temperature composites reinforced with refractory metal filaments, and refractory metal-based intermetallics, e.g., Nb3Al, Nb2Be17, and MoSi2, are briefly described.

A STATE VARIABLE MATERIAL MODEL FOR SUPERPLASTIC TITANIUM-6 PERCENT Al-4 PERCENT V Ph.D. Thesis
Daniel Abbott Mosher 1993 140 p
Avail: Univ. Microfilms Order No. DA9318816

A material model has been developed for the superplastic titanium alloy, Ti-6Al-4V, which describes the material's large strain viscoplastic behavior. To simulate superplastic forming, a model is required which captures the complexities of the material's mechanical response. The primary challenges to develop an accurate model are to determine which microstructural features are significant, the manner in which they influence the flow kinetics, and the rate at which these features evolve during thermomechanical processing. The two phase alpha-beta titanium alloy of this study has numerous aspects of the microstructure which could affect flow, as well as having multiple deformation mechanisms. In this work, the alpha phase grain size and shape have been used to represent the

microstructural state. Physical experiments have been performed to obtain data on the uniaxial kinetics of flow at fixed microstructural state and the evolution of state. The uniaxial kinetics have been determined over the following ranges of uniaxial deformation rate, d, temperature, T, and alpha grain size, bar-L(sub 3) (exp eff): 10(exp -5) s(exp -l) less than d less than 10(exp -3) s(exp -1), 875 degrees C less than T less than 950 degrees C, and 5.7 microns less than bar-L(exp eff) (sub 3) less than 17.1 microns. A hyperbolic sine functional form has been developed to capture the uniaxial behavior, which is based on the transition between two deformation mechanisms. An orthotropic flow rule has been derived based on alpha grain shape, which adds only one additional parameter that can be evaluated through uniaxial tests and microstructural examination. Grain size evolution experiments have been performed at 900 and 925 degrees C over the ranges of d and L(exp eff) (sub 3) given above. Grain growth has been divided into static and deformation enhanced components. Functional forms and material parameters have been determined which closely match the path dependent change of alpha grain size. The use of alpha grain size as an estimate of the microstructural state captures some of the transients observed in the stress response. Other trends such as strain softening cannot be predicted by the model, implying that additional aspects of the microstructure play a significant role in the kinetics of flow. Dissert. Abstr.

N94-32514# Argonne National Lab., IL.
STRUCTURAL ORDERING IN LIQUID K-Te ALLOYS
J. Fortner, M. L. Saboungi, and J. E. Enderby 1994 9 p
(Contract W-31-109-eng-38)
(DE94-008477; ANL/CMT/PP-75501) Avail: CASI HC A02/MF A01

Neutron diffraction from molten K(sub x)Te(sub 1-x) is reported for x = 0.12 and x = 0.50 semiconducting alloys. The measured radial distribution functions (rdf) demonstrate the persistence of covalently bonded tellurium in the liquid. The rdf of the liquid K(sub 0.12)Te(sub 0.88), which is dominated by the Te-Te contribution, is remarkably similar to that of pure liquid tellurium, the notable exception being that the nearest neighbor peak is largely resolved and found to have a coordination number slightly less than 2. The K(sub 0.50)Te(sub 0.50) rdf clearly indicates Te-Te pairing in the melt, and unexpected departure from the presumed similar Cu(sub 0.50)Te(sub 0.50). These paired tellurium are most likely of the form (Te(sub 2))(sup 2-) Zintl ions. DOE

LIQUID-ASSISTED DIFFUSION BONDING OF NiAl
M. J. Strum and G. A. Henshall 1994 15 p Presented at the 2nd Advanced Joining Technologies for New Materials, Cocoa Beach, FL, 2-4 Mar. 1994
(Contract W-7405-eng-48)
(DE94-008687; UCRL-JC-115737; CONF-940367-2) Avail: CASI HC A03/MF A01

A new isothermal joining method is investigated which could allow full utilization of the high temperature properties of advanced intermetallic alloys, such as NiAl, by producing joint compositions which match the parent material after bonding. In this method, interlayers of the parent material constituents are pre-placed in stoichiometric proportions on the surfaces to be joined. Bonding occurs without the application of pressure by raising the temperature above the liquidus of the lower melting constituent. The constituents then interdiffuse to produce the parent material phase and homogenize to the proper stoichiometry. This method differs from conventional liquid-assisted diffusion bonding in that no foreign melting-point depressants are added. Interrupted bonding treatments were used to characterize the kinetics of the isothermal solidification and homogenization processes in NiAl couples, and the compositional profiles of the bond region were characterized by electron probe microanalysis. Homogenization, as defined by the Ni and Al concentration maxima, follows a logarithmic time dependence once the bond region becomes single-phase NiAl. DOE

STAGE 1 BEHAVIOR IN A STRESS CORROSION STUDY OF TYPE 304 STAINLESS STEEL
A. L. Lund (Washington State Univ., Richland.) and R. H. Jones 1994 13 p Presented at the Corrosion 1994: National Association of Corrosion Engineers (NACE) International Annual Conference, Baltimore, MD, 28 Feb. - 4 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC06-76RL-01830)
(DE94-008054; PNL-SA-23410; CONF-940222-13) Avail: CASI HC A03

In stress corrosion studies, crack velocity plotted with respect to stress intensity generally yields a characteristic curve with three distinct regions. Stage 1 exhibits a threshold (K(sub ISCC)) followed by a rapid increase in crack velocity (da/dt) for small changes in stress intensity. Stage 2 is characterized by an essentially constant crack velocity with increases in the stress intensity. Stage 3 exhibits a rapid increase in crack velocity for small increases in stress intensity leading to fracture. Stage 1 behavior has been poorly characterized in literature due to previous emphasis on determining the threshold K(sub ISCC) and difficulty and uncertainty in measuring of a large increase in crack velocity with only incremental changes in stress intensity. Tests were conducted in the stage 1 regime to measure crack velocity as a function of constant stress intensity. Constant K specimens were prepared according to the Mostovoy design, a tapered double cantilever beam. Specimens were prepared from Type 304 stainless steel containing 0.06 weight percent C solution annealed at 1100 C for 1 hour, water quenched, and annealed at 625 C for 24 hours to produce sensitization. A sodium thiosulfate solution at 50 C was chosen as the test environment. DOE

Pure silver and aluminum powders have been mechanically alloyed in a Spex mill. Four selected nominal compositions Ag(1-x)Al(x) (x = 0.20, 0.23, 0.26 and 0.37) were investigated by X-ray diffraction and differential scanning calorimetry, after being subjected to different times of ball milling. In all four selected compositions, the close packed hexagonal intermediate lambda-phase and the fcc alpha-phase (Ag-based solid solution) formed together during the first hour of milling, but subsequently the lambda-phase disappeared during continued milling except in the two alloys corresponding to 26 at.%Al and 37 at.%Al where the lambda-phase is the equilibrium phase. With continued milling, the complex cubic mu-phase formed in the alloys of nominal composition 20, 23 and 26 at.%Al where it is expected in equilibrium alloys. No amorphous phases have been observed in the mechanically alloyed powders in this system. DOE

GETTERING OF METAL IMPURITIES BY CAVITIES IN SILICON
S. M. Myers, D. M. Follstaedt, D. M. Bishop, and J. W. Medernach 1993 12 p Presented at the 7th International Conference on Silicon Materials Science and Technology, San Francisco, CA, 22-27 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-94AL-85000)
(DE94-005248; SAND-93-2047C; CONF-940537-1) Avail: CASI HC A03

Ion implantation of He into Si followed by annealing approximately greater than 700 C produces nanometer-scale cavities from which the He has diffused. Experiments utilizing Rutherford backscattering spectrometry and transmission electron microscopy show that these cavities trap Cu impurities with a binding energy of 2.2 +/- 0.2 eV relative to solution, whereas the binding energy in precipitates of the equilibrium silicide phase Cu3Si is determined to be 1.7 eV. Preliminary results indicate that Ni impurities also are bound more strongly at internal surfaces than in silicide precipitates. These findings suggest that cavity traps may provide exceptionally effective gettering of transition-metal impurities. Additional properties relevant to gettering are discussed, including fundamental differences between trapping and precipitation dynamics, the replacement of Cu by H atoms at internal surface sites cavity-associated electronic levels in the band gap, and microstructural stability of the cavities. CHARACTERIZATION OF THE CORROSION RESISTANCE OF DUPLEX STAINLESS STEELS USING LOCAL CURRENT DENSITY MAPPING TECHNIQUES
A. Aldykiewicz and H. S. Isaacs 10 Jan. 1994 23 p
(Contract DE-AC02-76CH-00016)
(DE94-007980; BNL-60099) Avail: CASI HC A03/MF A01

An in situ investigation of the dissolution behavior of duplex stainless steel has been carried out in acidic solutions containing 2.0 M HCl with 2.0 M H2SO4 to determine differences in dissolution rates of the austenitic and ferritic phases. The current density distribution over the dissolving steel surface was measured using a vibrating electrode. The study demonstrated that this technique could quantify the differences in dissolution rates of the austenitic and ferritic phases under the conditions tested. The dissolution rates for the two phases peak at different potentials resulting in multiple current maxima. In addition, transients in dissolution behavior of the two phases at different potentials were observed using optical microscopy. Electron microscopy of the dissolved surface showed very high levels of aluminum and silicon enrichment on the austenitic phase.

CALCULATIONS OF NONSPHERICALLY AVERAGED CHARGE DENSITIES FOR SUBSTITUTIONALLY DISORDERED ALLOYS
P. P. Singh and A. Gonis Feb. 1994 9 p Presented at the NATO Advanced Study Workshop on Metallic Alloys: Experimental and Theoretical Perspectives, Boca Raton, FL, 16-21 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-008293; UCRL-JC-116372; CONF-930759-7) Avail: Issuing Activity (Department of Energy (DOE))

Based on screening transformations of muffin-tin orbitals introduced by Andersen et al., we have developed a formalism for calculating the nonspherically averaged charge densities of substitutionally disordered alloys using the Korringa - Kohn - Rostoker coherent potential approximation (KKR CPA) method in the atomic-sphere approximation (ASA). We have validated our method by calculating charge densities for ordered structures, where we find that our approach yields charge densities that are essentially indistinguishable from the results of full-potential methods. For substitutionally disordered alloys, where full-potential methods have not been implemented so far, our approach can be used to calculate reliable nonspherically averaged charge densities from spherically symmetric one-electron potentials obtained from the KKR-ASA CPA. We report on our study of differences in charge denisty between ordered AlLi in L1(sub o) phase and substitutionally disordered Al(0.5)Li(0.5) on face-centered cubic lattice.

DEUTERIUM ABSORPTION AND MATERIAL PHASE CHARACTERISTICS OF SAES St198 Zr-Fe ALLOY
A. Nobile, W. C. Mosley, J. S. Holder, and K. N. Brooks Jan. 1994 36 p Revised
(Contract DE-AC09-89SR-18035)
(DE94-008275; WSRC-TR-92-557-Rev-1) Avail: CASI HC A03/MF A01

This document reports deuterium absorption and material phase characteristics of SAES St 198 Zr-Fe Alloy (76.5% Zr). Scanning electron microscope images of polished surfaces, electron probe microanalysis, and x-ray powder diffractometry indicated the presence of a primary Zr2Fe phase with secondary phases of ZrFe2, Zr5FeSn, alpha-Zr, and Zr6Fe3O. A statistically designed experiment to determine the effects of temperature, time, and vacuum quality on activation of St 198 revealed that, when activated at low temperature (350 C), deuterium absorption rate was slower when the vacuum quality was poor (2.5 Pa vs. 3 x 10(exp -4) Pa). However, at higher activation temperature (500 C), deuterium absorption rate was fast and was independent of vacuum quality. Deuterium pressure-composition-temperature (P-C-T) data are reported for St 198 in the temperature range 200 to 500 C. The P-C-T data over the full range of deuterium loading and at temperatures of 350 C and below is described an expression. At higher temperatures, one or more secondary reactions in the solid phase occur that slowly consume D2 from the gas phase. X-ray diffraction and other data suggest these reactions to be: 2Zr2FeD(x) yields xZrD2 + x/3 ZrFe2 + (2 - 2/3x) Zr2Fe and Zr2FeD(x) + (2 - 1/2x) D2 yields 2ZrD2 + Fe, for 0 less than x less than 3. Reaction between gas-phase deuterium and Zr2Fe formed in the first reaction accounts for the observed consumption of deuterium from the gas phase by this reaction.

ANISOTROPIC PHASE SEPARATION THROUGH THE METAL-INSULATOR TRANSITION IN AMORPHOUS Mo-Ge AND Fe-Ge ALLOYS Ph.D. Thesis
M. J. Regan Dec. 1993 152 p
(Contract DE-AC03-76SF-00515)
(DE94-007259; SU-SLAC-427; SU-SLAC/SSRL-0061) Avail: CASI HC A08/MF A02

Since an amorphous solid is often defined as that which lacks long-range order, the atomic structure is typically characterized in terms of the high-degree of short-range order. Most descriptions of vapor-deposited amorphous alloys focus on characterizing this order, while assuming that the material is chemically homogeneous beyond a few near neighbors. By coupling traditional small-angle x-ray scattering which probes spatial variations of the electron density with anomalous dispersion which creates a species-specific contrast, one can discern cracks and voids from chemical inhomogeneity. In particular, one finds that the chemical inhomogeneities which have been previously reported in amorphous Fe(x)Ge(1-x) and Mo(x)Ge(1-x) are quite anisotropic, depending significantly on the direction of film growth. With the addition of small amounts of metal atoms (x less than 0.2), no films appear isotropic nor homogeneous through the metal/insulator transition. The results indicate that fluctuations in the growth direction play a pivotal role in preventing simple growth models of a columnar structure or one that evolves systematically as it grows. The anomalous scattering measurements identify the metal atoms (Fe or Mo) as the source of the anisotropy, with the Ge atoms distributed homogeneously. The author has developed a method for using these measurements to determine the compositions of the phase-separating species. The results indicate phase separation into an amorphous Ge and an intermetallic phase of stoichiometry close to FeGe2 or MoGe3. Finally, by manipulating the deposited power flux and rates of growth, Fe(x)Ge(1-x) films which have the same Fe composition x can be grown to different states of phase separation. These results may help explain the difficulty workers have had in isolating the metal/insulator transition for these and other vapor-deposited amorphous alloys.

POTENTIAL APPLICATIONS OF FUSION NEUTRAL BEAM FACILITIES FOR ADVANCED MATERIAL PROCESSING
J. M. Williams, C. C. Tsai, W. L. Stirling, and J. H. Whealton Jan. 1994 21 p Presented at the Workshop on Plasma-Based Ion Implantation, Madison, WI, 4-6 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-009167; CONF-9308156-3) Avail: CASI HC A03

Surface processing techniques involving high energy ion implantation have achieved commercial success for semiconductors and biomaterials. However, wider use has been limited in good part by economic factors, some of which are related to the line of sight nature of the beam implantation process. Plasma source ion implantation is intended to remove some of the limitations imposed by directionality of beam systems and also to help provide economies of scale. The present paper will outline relevant technologies and areas of expertise that exist at Oak Ridge National Laboratory in relation to possible future needs in materials processing. Experience in generation of plasmas, control of ionization states, pulsed extraction, and sheath physics exists. Contributions to future technology can be made either for the immersion mode or for the extracted beam mode. Existing facilities include the High Power Test Facility, which could conservatively operate at 1 A of continuous current at 100 kV delivered to areas of about 1 m(exp 2). Higher instantaneous voltages and currents are available with a reduced duty cycle. Another facility, the High Heat Flux Facility, can supply a maximum of 60 kV and currents of up to 60 A for 2 s on a 10 percent duty cycle. Plasmas may be generated by use of microwaves, radio frequency induction, or other methods and plasma properties may be tailored to suit specific needs. In addition to ion implantation of large steel components, foreseeable applications include ion implantation of polymers, ion implantation of Ti alloys, Al alloys, or other reactive surfaces. DOE

STRUCTURE, STABILITY, AND MECHANICAL PROPERTIES OF INTERMETALLIC PHASES
J. H. Schneibel and C. T. Liu 1993 13 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-009178; CONF-931009-22) Avail: Issuing Activity (Department of Energy (DOE))

The importance of the structural stability of intermetallics with regard to their mechanical properties is illustrated with two case studies. First, the importance of structural and thermal defects for the strength of (weakly ordered) FeAl and (strongly ordered) NiAl is shown. Several inconsistencies and unresolved issues in the present understanding of point defects in FeAl are addressed. Since point defects alone may not explain the mechanical differences between these two materials, the role of dislocations is considered as well. It is shown that the differences in the atomic bonding of FeAl and NiAl, which determine the active slip systems, are likely to influence the compositional dependence of the strength of these two intermetallics. Second, the class of the trialuminides is reviewed with emphasis on Al3Ti. In addition to stabilizing a cubic crystal structure, the ratio of K/G, where K is the bulk modulus and G the shear modulus, needs to be increased in order to achieve extensive plastic deformation at room temperature. It is not clear, at the present time, to what extent macroalloying of trialuminides can achieve this goal, although promising results have been reported for Al3Ti containing relatively high concentrations (14 at. %) of chromium. DEPENDENCE OF X RAY ABSORPTION MAGNETIC CIRCULAR DICHROISM ON LAYER PERIODICITY IN IRON-PLATINUM MULTILAYERS
A. F. Jankowski, G. D. Waddill, and J. G. Tobin Nov. 1993 14 p Presented at the 40th National Symposium of the American Vacuum Society, Orlando, FL, 15-19 Nov. 1993
(Contract W-7405-eng-48)
(DE94-008786; UCRL-JC-115359; CONF-9311104-20) Avail: CASI HC A03/MF A01

Magnetic circular dichroism in x-ray absorption is observed in Fe/Pt multilayers. The magnetization and helicity are both in the plane of the Fe/Pt multilayers which are prepared by planar magnetron sputter deposition. Lattice and layer pair spacings are measured using grazing incidence and high angle x-ray scattering. The film composition and lattice growth are confirmed using Auger depth profiling and cross-section transmission electron microscopy, respectively. The state of the film magnetization is found to be dependent on the layer pair spacing as well as the relative thickness of the Fe to Pt layer. The maximum magnetic moment is measured for a (Fe (9.5 A)/Pt (9.5) A)(sub 92) multilayer. DOE

FRICTIONAL BEHAVIOR AND ADHESION OF Ag AND Au FILMS APPLIED TO ALUMINUM OXIDE BY OXYGEN-ION ASSISTED SCREEN CAGE ION PLATING (SCIP)
Talivaldis Spalvins and Harold E. Sliney Apr. 1994 13 p Presented at the ICMCTF 1994, San Diego, CA, 25-29 Apr. 1994; sponsored by the American Vacuum Society
(RTOP 505-63-5A)
(NASA-TM-106522; E-8645; NAS 1.15:106522) Avail: CASI HC A03/MF A01

A modified dc-diode ion plating system, by utilizing a metallic screen cage as a cathode, is introduced for coating nonconductors such as ceramics. Screen cage ion plating (SCIP) is used to apply Ag and Au lubricating films on aluminum oxide surfaces. This process has excellent ability to coat around corners to produce three-dimensional coverage of the substrate. A dramatic increase in adhesion is achieved when plating is performed in a reactive 50 percent O2 - 50 percent Ar glow discharge compared to the adhesion when plating is performed in 100 percent Ar. The presence of oxygen ion assistance contributes to the excellent adhesion as measured in a pull-type adhesion tester. The Ag and Au film adhesion is significantly increased (less than 70MPa) and generally exceeds the cohesion of the substrate such that portions of the alumina are pulled out. Author

EXPERIMENTAL STUDIES ON THE EFFECT OF COHERENCY STRAINS ON COARSENING KINETICS: CURRENT STATUS AND FUTURE OUTLOOK
G. Muralidharan, J. E. Epperson, and H. Chen 1994 12 p Presented at the International Conference on Advances in Physical Metallurgy, Bombay, India, 9-11 Mar. 1994
(Contracts W-31-109-eng-38; DE-FG02-91ER-45439)
(DE94-008480; ANL/IPNS/CP-82301; CONF-940383-1) Avail: CASI HC A03/MF A01

The effect of coherency strains on the coarsening rate constant in Ostwald ripening is an area that is not well understood. We briefly review the extant experimental data on the effect of coherency strains on coarsening rates and explain the need to account for variations in coarsening rates due to composition and diffusivity effects before drawing any conclusions on the dependence of coarsening rates on the misfit parameter. Using the preexisting theories for coarsening rates in multi-component systems, we suggest a simple method to account for the composition dependence of coarsening rates arising from factors unrelated to coherency strain effects. We then present some of the results from our on-going work in the Ni-Al-Si system and explain the relevance of this study to our understanding of coarsening in internally-stressed systems. We conclude the presentation with our views on the direction of future research in this aspect of coarsening. DOE

Ar-40 and Bi-209 ion irradiations of Zr3Fe were performed at 35-725 K using 15-1500 keV ions. Results are presented on the role of deposited-energy density on the nature of the damaged regions in individual cascades produced by ion bombardment of Zr3Fe. Comparison is also made between irradiation-induced amorphization of Zr3Fe during electron irradiation and under ion bombardments. Dependence of damage production on incident electron energy in Zr3Fe was also determined. Preliminary results are also discussed for amorphization of ZrFe2, Zr(Cr,Fe)2, and ZrCr2 by electron irradiation. Results of a recent investigation on amorphization of Zr(Cr,Fe)2 and Zr2(Ni,Fe) precipitates in Zircaloy-4 are discussed in the context of previous experimental results of neutron and electron irradiations and likely amorphization mechanisms are proposed. INDUCED ADSORPTION OF CHLORIDE AND BROMIDE BY SUBMONOLAYER AMOUNTS OF COPPER UNDERPOTENTIALLY DEPOSITED ON Pt(111)
R. Gomez, J. M. Feliu, and H. D. Abruna 14 Mar. 1994 43 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-84-K-0656)
(AD-A278023; TR-35) Avail: CASI HC A03

The underpotential deposition of submonolayer amounts of copper induces an enhanced adsorption of chloride and bromide on Pt(111) and is reflected in exceedingly sharp voltammetric peaks. The adsorbed anions are believed to be in contact with the platinum surface and in the vicinity of the electrodeposited copper. The electrosorption valency for chloride anions was estimated to be about one. This effect of induced adsorption was not observed on Pt(100) pointing to the sensitivity of the process to the surface structure. The advantages of working with low concentrations of metals in UPD studies is illustrated. DTIC

PHASE RELATIONSHIPS AND STABILITY OF THE (MU)- AND (ZETA)-PHASES IN THE Ag-Al-X (X=Zn, Ga, Ge) SYSTEMS
M. R. Paruchuri and T. B. Massalaski Sep. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-009391; UCRL-CR-114778) Avail: CASI HC A03

Details of phase relationships in three ternary systems, Ag-Al-X (X=Zn, Ga, Ge) near the Ag-rich corner at 400 C are presented. Metallography, x-ray diffraction, scanning electron microscopy and x-ray spectroscopy have been used to establish the respective isothermal sections at 400 C. In each case, the mu-phase and the zeta-phase of the Ag-Al binary system extend into the ternary system and terminate at a three-phase region involving the Ag-rich primary solid solution (alpha(sub 1)-phase) in the Ag-Al-Zn and Ag-Al-Ga systems, and the Ge-rich primary solid solution (alpha(sub 2)-phase) in the Ag-Al-Ge ternary system. The stability ranges of the mu and zeta-phases follow approximately constant electron concentration lines. The solid solubilities of Zn, Ga and Ge in the mu-phase are relatively small, compared with those in the zeta-phase (up to 18 at. %). No ternary phase appears to exist in the Ag-rich portions studied in the three ternary systems. DOE

SIMPLER J(SUB Ic) TEST AND DATA ANALYSIS PROCEDURES FOR HIGH STRENGTH STEELS Final Report
J. H. Underwood, E. J. Troiano, and R. T. Abbott Jan. 1994 27 p
(AD-A277731; ARCCB-TR-94001) Avail: CASI HC A03/MF A01

Tests of five medium and high strength steels were used to investigate some prospective simplification in J(sub Ic) test and data analysis procedures. Three-point bend specimens with material strengths of 500 to 1500 MPa and nominal thickness of 10 mm were tested at room temperature. The investigation included J(sub Ic) tests using measured crack-mouth displacement to calculate load-line displacement based on an expression that relates the two displacements; a simple zero-point adjustment for J versus Delta-a curves, whereby certain intermediate Delta-a values are shifted to the blunting line to correct for errors at low values of Delta-a; and a comparison of Delta-a and J(sub Ic) results from the load-drop method, which gives a simple measure of crack growth after maximum load, with results from the usual unloading compliance method. The various results and comparisons are discussed in relation to their usefulness as general J(sub Ic) test procedure for a variety of materials, or a limited use test for certain materials. Two specific test and data procedures are proposed for general use in J(sub Ic) testing as follows. A new expression is described that calculates load-line displacement for the bend specimen from measured crack-mouth displacement, for a range of a/W values and strain hardening exponents. The expression makes possible a single-displacement unloading compliance J(sub Ic) test for the bend specimen using a single, standard, crack-mouth clip gage. A simple zero-shift procedure is proposed for general use with J(sub Ic) tests and for addition to ASTM Method E-813. The procedure adjusts the zero point of Delta-a so that on average the Delta-a values lie on the blunting line over the J-range of 20 to 60 percent of the provisional fracture toughness, J(sub Q). (AD-A276207; ONREUR-93-7-R) Avail: CASI HC A24/MF A04

The Office of Naval Research (ONR) and Office of Naval Research European Office (ONR Europe) recently sponsored an international workshop on advances in piezoelectric materials and current research thrusts in Europe. 'Perspectives on Piezoelectric Materials Research' was held at Elvetham Hall, near Basingstoke, England, 21-24 Feb. 1993. The 27 invited delegates were drawn from industry, academia, and government research organizations in nine countries: Denmark, France, the Federal Republic of Germany (FRG), Italy, Slovenia, Spain, Switzerland, the United Kingdom (U.K.), and the United States (U.S.). Abstracts and viewgraphs from the international meeting have been included in this report. DTIC

REACTIONS OF ELECTROPHILIC MALEIC ANHYDRIDE AND EPOXY GROUPS WITH NUCLEOPHILIC FUNCTIONALITIES SUCH AS CARBOXYL, HYDROXYL, AND AMINE GROUPS. POLYMER TECHNOLOGY PUBLICATION SERIES NO. 16 Literature Review
P. Hietaoja and R. Holsti-Miettinen Aug. 1993 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0785-7144)
(PB94-135589; ISBN-951-22-1712-0) Avail: Issuing Activity (National Technical Information Service (NTIS))

The desired chemical reactions which may take place under twin screw extruder conditions have been reviewed. Effects of time, temperature, and catalysts have been summerized. Applications for polymer blending have been discussed. The study of chemical reactions between two polymers is often very complicated and therefore most of the work has been made with low molecular weight monomers or oligomers. NTIS

EVALUATION OF CORROSION PROTECTIVE ORGANIC COATINGS FOR STEEL STRUCTURES IN FRESH WATER Final Report
U. Steinsmo 9 Aug. 1993 40 p
(PB94-138484; STF34-A93158) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report presents a summary of the final results from a 6 year program 'Evaluation of Corrosion Protective Organic Coatings for Steel Structures in Fresh Water'. 76 paint systems from 19 different main suppliers have been tested. The test program involved three different humidity cabinet tests, two water immersion tests, and long term exposure test in fresh water at three different fresh water sites and in cold humid air in two mountain tunnels. The importance of microbial activity has been investigated. In addition water uptake and water diffusivity have been determined and electrochemical studies performed. NTIS

A COMPATIBILITY STUDY OF FEFO WITH VARIOUS CONTAINMENT MATERIALS
T. J. Shepodd, S. H. Goods, and P. Foster 1994 6 p Presented at the International Symposium on Energetic Materials Technology and Exhibits, Orlando, FL, 21-24 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005753; SAND-94-8508C; CONF-940348-2) Avail: CASI HC A02/MF A01

Compatibility between fluid bis-(2-fluoro- 2,2-dinitroethyl) formal (FEFO) and a number of organic and metallic materials was evaluated at 22 and 74 C for up to 8 months. The metals included common structural alloys and elemental metals that the extrudable explosive might contact in its service life. The organic materials included flexible materials for use as collapsible extrusion membranes or permeation barriers, rigid engineering resins (matrices for composite vessels), and polymer viscosity modifiers. SOL-GEL METAL OXIDE AND METAL OXIDE/POLYMER MULTILAYERS APPLIED BY MENISCUS COATING
J. A. Britten and I. M. Thomas Oct. 1993 9 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-005813; UCRL-JC-114730; CONF-931054-5) Avail: CASI HC A02/MF A01

We are developing a meniscus coating process for manufacturing large-aperture dielectric multilayer high reflectors (HR's) at ambient conditions from liquid suspensions. Using a lab-scale coater capable of coating 150 mm square substrates, we have produced several HR's which give 99% + reflection with 24 layers and with edge effects confined to about 10 mm. In calendar 1993, we are taking delivery of an automated meniscus coating machine capable of coating substrates up to 400 mm wide and 600 mm long. The laser-damage threshold and failure stress of sol-gel thin films can be substantially increased through the use of soluble polymers which act as binders for the metal oxide particles comprising the deposited film. Refractive index control of the film is also possible through varying the polymer/oxide ratio. Much of our present effort is in optimizing oxide particle/binder/solvent formulations for the high-index material. Films from colloidal zirconia strengthened with polyvinylpyrollidone (PVP) have given best results to date. An increase in the laser damage threshold (LDT) for single layers has been shown to significantly increase with increased polymer loading, but as yet the LDT for multilayer stacks remains low. DOE

MOLECULAR/POLYMERIC MAGNETISM
1993 13 p
(Contract DE-FG02-86ER-45271)
(DE94-005888; DOE/ER-45271/T7) Avail: CASI HC A03/MF A01

Accomplishments during this past grant period span three areas of research. (1) Following models the authors and others have proposed, they have synthesized numerous new materials to test the generality of magnetism in molecular/polymeric systems. This activity is capped by their disclosure of the first room temperature molecular based magnet V(TCNE)x y(soivent). (2) They have extensively studied the magnetic transitions and related phenomena in decamethylferrocenium tetracyanoethanide, (FeCp*2)(TCNE), V(TCNE)x(center dot)y(solvent), and related materials, and developed an initial understanding of the key roles played by disorder, anisotropy, dimensionality, and spin magnitude. They have tested theirs and others' models for the origin of magnetic exchange between local sites, and models for control of (Tc), determining successes and shortcomings. They briefly summarize here the major breakthroughs, accomplishments, and discoveries that have occurred during this period. DOE

AN INVESTIGATION OF THE SPIN-COATING PROCESS AND A MODEL FOR THREE-DIMENSIONAL REGULAR FOAMS Ph.D. Thesis
Weiqun Zhou 1993 153 p
Avail: Univ. Microfilms Order No. DA9329211

The thesis consists of two independent parts. The first part is entitled: An investigation of the spin-coating process; the second part is entitled: A model for three-dimensional regular foams. For spin-coating, a detailed numerical investigation of the spin-coating process has been performed. Our numerical approach takes advantage of the known asymptotic structure of the solution to the governing equations, and uses an adaptive scheme with multiple grids to achieve substantial improvements in accuracy and efficiency over previous approaches. As a result, the final coating thickness may be predicted, with good accuracy and efficiency, in terms of the spin speed and various material properties. For foam rheology, a model for the 3-D regular foam is developed. The 3-D model is considerably more realistic than the 2-D model used by previous researchers. The static shape of a foam cell is governed by the Young-Laplace equation, with one free boundary. The general problem was solved numerically, while asymptotic approximations were pursued for the limit of the gas volume fraction approaching unity. To study the rheology, we need to determine the geometry of the tessellating cells under deformation. To this end, a formalism is developed, which takes advantage of the affine movement of particular points of the tessellating cells (face centers, centroid of cell). Finally, as an example, the stretch of our 3-D model is examined in detail. Significant differences between the 3-D and 2-D models are observed. Most notably, the elastic modulus predicted by the 3-D model is lower and decreases faster with stretch than that predicted by the 2-D model, which suggests that the 3-D model might give closer agreement with experiments than the 2-D model. Results from a previous study carried out by the Lehigh group demonstrated Al2O3:SiC nanocomposites exhibited superior mechanical behavior relative to single phase alumina only when the samples had been annealed (2 h at 1300 C in argon) subsequent to industrial machining. These results were rationalized by postulating that on annealing of the machined specimens: (1) The extent of healing of grinding induced flaws is more significant in the nanocomposite than in alumina. (2) The machining induced residual stresses are relaxed to a lesser degree in the nanocomposite than in alumina. Further model studies have now been carried out which provide definitive evidence that both of the above assumptions are correct. Observation of indentation induced cracks both prior to, and after annealing, revealed that in the nanocomposite cracking

is predominantly transgranular, and crack healing takes place on annealing. For the case of single phase alumina, however, the crack morphology is predominantly intergranular, and annealing causes crack growth. DTIC

RELIABILITY OF MULTILAYER COPPER/POLYIMIDE Final Report
S. V. Babu, D. H. Rasmussen, and D. W. Lawrence Nov. 1993 24 p
(Contract F30602-88-D-0028)
(AD-A276228; RL-TR-93-215) Avail: CASI HC A03/MF A01

The reliability of copper/polyimide (PI) multilayer structures was analyzed and found to depend on processing and environmental conditions. Copper films were deposited by thermal evaporation and patterned by contact lithography. Preimidized P12590-D polyimide films were spin coated over the copper with upper layers deposited as required. While the electrical characteristics of the multilayer structures generally behaved as expected, the softening of the underlying PI films led to observation of film buckling and dielectric breakdown in some samples. Consequently, alternate low temperature plasma and laser techniques for depositing copper on PI films, instead of PI films on copper, were explored to improve the reliability of the resulting Cu/PI multilayer structures. Copper films were deposited on PI substrates by radio frequency (13.56 MHz) plasma-induced reduction and excimer laser-induced ablation of copper formate. While the Cu/PI interface appears clean, the reduction of the formate was not complete with some residual carbon contamination in the copper film. Several methods for improving the purity of the Cu films were investigated. Diamondlike carbon (DLC) films are excellent barriers for the diffusion of Cu in Cu/Si structures. DLC films, due to their excellent compatibility with PI, may play a similar useful role in Cu/PI structures and improve their reliability. DTIC

Molecular interactions between a substrate and an overlayer control the intrinsic adhesion between the two materials and this intrinsic adhesion, in turn, is a critical component of the measured adhesion which also includes factors related to plastic deformation of the materials. Because virtually all measurements of adhesion include these other factors, accurate values for the intrinsic adhesion have not been available in the past. To develop a means to measure this parameter, nonlinear von Karman plate theory has been used for a consistent analysis of pressurized circular, island and peninsula blister specimens. The configurations considered ranged from linear plates to membranes. Interfacial energy release rates and fracture mode-mixes were extracted. For a given pressure and all possible materials and delamination length to thickness (aspect, a/h) ratios, the peninsula blister provided the highest energy release rate, followed by the island and circular blisters. The extent of yielding in delaminating copper films was greatest with the circular blister. The stress levels in the island blister were notably lower. While extensive yielding was still present in peninsula blister configurations with a/h = 100 and 500, there was none for a/h = 10. A scheme for extending the utility of blister specimens to higher aspect ratios was developed and analyzed. DTIC

COST-EFFECTIVE CERAMIC MACHINING: SUMMARY OF THREE-BODY WEAR EXPERIMENTS
L. V. Griffith Nov. 1993 55 p
(Contract W-7405-eng-48)
(DE94-007757; UCRL-ID-115678) Avail: CASI HC A04/MF A01

Loose-abrasive grinding experiments were conducted to compare relative grinding rates of BK7 glass, Si nitride, and alumina zirconia. Si nitride and alumina zirconia machined at about the same rate, while BK7 glass machined 6-8 times faster. Surface finish and subsurface were measured. Surface roughness of the ceramics is better than that of glass. Empirical equations for relating roughness and Preston coefficients were only qualitatively successful. Diamond and B4C yield about the same removal rate, but this is not basis enough for recommending the cheaper abrasive for the fixed-abrasive machining process. B4C is more friable than diamond, producing sharp cutting surfaces; however B4C may not be a good abrasive for precision grinding. SiC produced excellent surface finish but low removal rates. DOE

RELIABILITY ANALYSIS OF STRUCTURAL CERAMICS SUBJECTED TO BIAXIAL FLEXURE Ph.D. Thesis
Luen-Yuan Chao 1993 153 p
Avail: Univ. Microfilms Order No. DA9319428

Two weakest-link fracture statistics formulations for multiaxial loading, Batdorf's flaw density and orientation distribution approach and Evans' elemental strength approach, were compared for identical fracture criteria and flaw-size distribution function. Despite some fundamental differences in the methodology used in calculating fracture probabilities for multiaxial loading, the two approaches gave identical predictions. A recent contradictory conclusion reported in the literature is shown to be incorrect. Fracture stresses of a sintered alumina and silicon nitride were assessed in qualified uniaxial (three-point and four-point) and biaxial (uniform-pressure-on-disk) flexure tests in inert conditions (dry N2, 100 MPa/s stressing rate). The size and stress-state effects on the inert fracture stress of alumina were explained by a reliability analysis based on randomly oriented surface flaws and a mixed-mode fracture criterion. Fracture stresses of silicon nitride were in accord with a reliability analysis based on volume flaws with preferred orientation (crack plane normal to the maximum principal stress) and a normal stress fracture criterion. The preferred orientation of the flaws in silicon nitride resulted from stress-induced nucleation of cracks around pores. Alumina ceramic was also tested in deionized water at a low stressing rate (1 MPa/s). The decreased fracture stresses measured in both uniaxial and biaxial flexure tests in water as compared to the inert fracture stresses were consistent with subcritical crack growth behavior inferred from dynamic fatigue tests in water. The analysis of the size and stress-state effects on and time-dependent degradation of fracture stresses included consideration of the statistical uncertainties (90 percent confidence intervals) of the estimated Weibull (Weibull modulus, m, and characteristic strength, sigma(sub theta)) and slow-crack-growth (stress-intensity exponent, N, and critical crack growth rate, V(sub C)) parameters. Results suggested that subcritical crack growth and strength degradation were more severe in biaxial flexure than in uniaxial flexure, which implies an interaction between stress state and subcritical crack growth. Statistical analysis and correlation between pore-size distribution and fracture stress distribution using the theory of extreme-value statistics is presented for a sintered silicon nitride. The pore size distribution on a polished surface of this material was characterized using an automatic optical image analyzer. The distribution measured on the two dimensional plane surface was transformed to a population (volume) distribution using the Schwartz-Saltykov diameter method. The population pore-size distribution and the distribution of the pore size at fracture origins were correlated by extreme-value statistics. Fracture stress distribution was then predicted from the extreme-value pore size distribution using a linear elastic fracture mechanics model of annular crack around pore and the fracture toughness of the ceramic. The predicted strength distribution was in good agreement with strength measurements in bending. In particular, the extreme-value statistics analysis explained the nonlinear trend in the linearized Weibull plot of measured strengths without having to postulate a lower-bound strength. Dissert. Abstr.

NOVEL ELECTROACTIVE POLYMERS AND BLOCK COPOLYMERS Final Report, 15 Aug. 1989 - 14 Aug. 1993
Ishrat M. Khan 12 Oct. 1993 12 p
(Contract DAAL03-89-G-0087)
(AD-A276119; ARO-27141.7-CH-SM) Avail: CASI HC A03/MF A01

Synthesis, characterization and properties of microphase separated mixed (ionic and electronic) conducting or MIEC block copolymers are reported. Polyomega-methoxyocta (oxyethylene)methacrylate-block-4-vinylpyridine, abbreviated as PMG8-4VP, and poly3-methylthiophene-block-omega-methoxyocta (oxyethylene)methacrylate, abbreviated as P(3MT-MG8), have been synthesized. Both block copolymer series may be appropriately doped to generate separate electronic and ionic conducting microdomains in the overall solid matrix. Also, highly ionic conductive solid polymer electrolytes have been prepared by blending poly(ethylene oxide), poly(2- or 4-vinylpyridine) and LiC1O4. All blends were prepared by the

solution blending process. Optimum blend compositions have been determined such that dimensionally stable elastomeric materials with ionic conductivities around 10(exp -5)S/cm at 25 C are obtained. DTIC

The performance and behavior of enzymes in non-aqueous environments has been explored under a variety of conditions, including high temperature and pressure. This work is both of fundamental interest, for providing information on enzyme behavior in non-aqueous environments, as well as of industrial importance, in that commercial processes which could benefit from the use of enzymes often operate in organic solvent, or at temperatures and pressures far from ambient. The work was directed at several topics within this general theme, including (1) biocatalysis in supercritical fluids--a study of the effect of smooth variations in solvent properties on enzyme activity; (2) biocatalysis in microemulsion systems--a study of the effect of microemulsion system variables on enzyme solubilization and activity; and (3) spectroscopic investigation of subtilisin in organic solvent--a study of the conformation of an enzyme in organic solvent as compared to its conformation in aqueous solution. COMPETITION BETWEEN CRYSTALLIZATION AND MIXING/DEMIXING IN POLYMER MIXTURE Ph.D. Thesis [KONKURRENZ ZWISCHEN KRISTALLISATION UND MISCHEN/ENTMISCHEN IN POLYMERMISCHUNGEN]
Yong Li 1991 143 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95753) Avail: CASI HC A07

The competition between crystallization and mixing/demixing was systematically studied in polymer systems, as well as their mutual influence and the resulting morphologies and overmolecular structures, taking as example the model system poly-epsilon-caprolacton/polystyrol. The correlation between structure formation and the preparative parameters was determined. The characteristics of the structures resulting from the two opposite processes were analyzed. The resulting structure was especially characterized as a function of the temperature and the composition of the mixture, with a view to the multiphasic nature of the overmolecular structure. It is shown that the morphology of a polymer system can be adjusted by controlling the competition crystallization and mixing/demixing. ESA

ELECTROSTATIC REDUCTION OF PARTICULATES FOR LASER RESISTANT HAFNIA COATINGS
M. D. Miller, R. Chow, and G. E. Loomis Dec. 1993 8 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-005824; UCRL-JC-114845; CONF-931054-3) Avail: CASI HC A02/MF A01

The authors have reduced by 50% particulate defect density of hafnia coatings deposited onto silicon substrates through the use of electric fields, physical barriers and deposition rate. In an effort to reduce the number of hafnia (HfO2) particulates deposited onto silicon wafers, parallel plate electrodes were placed on either side of the evaporant plume. The particulate level was determined as the deposition rate was varied from 0.75 angstrom/sec to 12 angstrom/sec. Then, parallel plate electrodes were placed on either side of the plume as a way of electrostatically deflecting hafnia particulates away from the substrates. Later a single plate electrode was used in conjunction with a physical barrier placed over the hearth. The results of the study indicate that minimal defects occur when a parallel plate electric field is applied in conjunction with a fast deposition rate. Using a screen as a physical barrier, and/or a single electrode had little or no effect. This data may be useful in the manufacture of multilayer optical coatings with high laser damage thresholds. SMALL CYLINDRICAL ADHESIVE BONDS Ph.D. Thesis
H. Poulis May 1993 149 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148210) Avail: Issuing Activity (National Technical Information Service (NTIS))

During the last few years, problems have arisen with regard to the adhesive bonding of very small cylindrical parts. The aim of this thesis is to design a practical and basic guidance for engineers in order to optimize the design and facilitate the production of small cylindrical adhesive bonds with a minimum number of production steps, but in such a way that the results are as reproducible as possible. The suggestions with regard to an optimal bond strength and performance are based on a large number of experimental values as well as on finite element analyses. NTIS

ADSORPTION OF WATER TO THE METAL/POLYMER INTERFACE STUDIED BY NEUTRON AND X RAY REFLECTIVITY
M. S. Kent, D. C. McIntyre, G. S. Smith, S. Baker, S. Wages, A. Nyitray, and J. Browning 1993 3 p Presented at the 17th Annual Adhesion Society Meeting, Orlando, FL, 20-24 Feb. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005578; SAND-93-3863C; CONF-940244-1) Avail: CASI HC A01/MF A01

Neutron reflectivity is among the few techniques able to probe a buried interface. Through the use of isotopic labeling, complicated interface structures may be determined with a resolution on the order of 5 angstroms. However, for highly complex thin film and interface structures, it is often necessary to perform complementary experiments to reduce the number of unknown variables, and thus enable an unambiguous interpretation of the neutron reflectivity. To this end, the authors have combined x-ray and neutron reflectivity to study changes in a metal/polymer interface (molybdenum/polyurethane, hereafter Mo/PU) upon exposure to a humid environment. In particular, the authors have tracked the adsorption of moisture to the interface and variations in the density of the interphase. This information was obtained as a function of the concentration of a silane coupling agent added to the bulk of the PU. Adhesion of the Mo/PU interface is important to programs in the DOE complex. This paper reports the first results of this study. DOE

(DE94-005583; SAND-93-1544C; CONF-931108-51) Avail: CASI HC A02/MF A01

Diamond-like carbon films were prepared by high intensity pulsed ion beam ablation of graphite targets. A 350 key, 35 kA, 400 ns pulse width beam, consisting primarily of carbon ions and protons, was focused onto a graphite target at a fluence of 15-45J/cm(sup 2). Films were deposited onto substrates positioned i.n q n angular array from normal to the target to 90 degrees off normal. Deposition rates up to 30 nm per pulse, corresponding to an instantaneous deposition rate greater than 1 mm/sec, have been observed. Electrical resistivities between 1 and 1000 ohm-cm were measured for these films. XRD scans showed that no crystalline structure developed in the films. SEM revealed that the bulk of the films contain material with feature sizes on the order of 100 nm, but micron size particles were deposited as well. Both Raman and electron energy loss spectroscopy indicated significant amounts of sp(sup 3) bonded carbon present in most of the films. DOE

SPACE HYPERVELOCITY MICROPARTICLE IMPACT DAMAGE IN POLYMER MATRIX COMPOSITES M.S. Thesis
Gerald N. Manuelpillai 1993 129 p
(ISBN-0-315-87057-5; CTN-94-61246) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The current state of knowledge concerning micrometeoroid, orbital debris, and hypervelocity impacts in space environments is reviewed. A database of hypervelocity impact effects on advanced composite materials was compiled, using data from both space- and ground-based systems. Particular emphasis was placed on data from the Long Duration Exposure Facility (LDEF) satellite. Experiments were performed to obtain data on hypervelocity impacts on impact damaged protective coatings on polymer matrix composites. Current NASA models for predicting micrometeoroid and orbital debris fluxes in earth vicinity and an impact fluence nomogram, which was developed using LDEF data, are detailed. The nomogram enables the user to estimate total impact damage over time for a given spacecraft size and orbit. The experimentally obtained impact damage data were also modelled in a manner similar to the LDEF data. Both linear and quadratic fits were obtained. An attempt was made to integrate the simulation and flight databases. By modifying the data to reflect the difference in materials and in impact angles, the simulation data matched the flight database quite well. CISTI

EMPIRICAL OPTIMIZATION OF THE CONSOLIDATION OF THERMOPLASTIC PREPREGS M.S. Thesis [OPTIMISATION EMPIRIQUE DE LA CONSOLIDATION DES PREIMPREGNES THERMOPLASTIQUES]
Tsevi M. G. Vovor Jun. 1993 158 p In FRENCH
(ISBN-0-315-86455-9; CTN-94-61198) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Response surface methodology, a statistical method of optimization, is used to relate the degree of consolidation of prepreg thermoplastic composites to their processing parameters. A global consolidation index is obtained from partial indices related to common mechanical properties such as shear strength, giving a quantitative formulation of the rather qualitative notion of consolidation, and provides an objective function for optimization. Fractional multifactorial designs were used in the experimental runs, involving various combinations of the processing parameters (temperature, pressure, residence time). Regression polynomial models were then built, using the least squares based response surface approach. Analysis of the polynomial coefficients showed the relative importance of the processing parameters and their respective interactions. For both amorphous polycarbonate glass and semicrystalline polypropylene glass prepregs, processing temperature was the most important parameter. For the amorphous system, the main interaction was temperature residence time. For the other, pressure residence time and pressure cooling rate interactions are among the important effects. The saddle nature of the fitted surfaces suggests nonexistence of a well defined optimal zone in the region investigated. Author (CISTI)

VISCOELASTIC FRACTURE CHARACTERIZATION OF POLYMERIC SOLIDS Ph.D. Thesis
Jin Seong Choi 1993 202 p
Avail: Univ. Microfilms Order No. DA9328700

Almost all engineering materials exhibit creep and relaxation behavior. The observed magnitude depends on temperature, stress level, and loading duration. Some polymers are further influenced by moisture contents as well. Attempts to predict the crack initiation and propagation in fracture of polymeric solid materials are complicated by all such variables. In this study, hard viscoelastic polymeric solid materials were used to develop the viscoelastic fracture characterizing parameter. Fracture mechanism at the crack tip or in the neighborhood of crack tip is affected by those time-dependent material behaviors. A continuum aspect of time-dependent fracture mechanics approach was utilized. In the time-independent material, a fracture mechanics theory has been well established. However, viscoelastic polymeric solids are the time-dependent materials, and analysis methods are more complicated due to the time-dependency and therefore, analysis methods are rare. In this study, single specimen test method called 'calibration curve' method was used. A hyperbolic tangent function was introduced as a new calibration function to develop the whole crack growth resistance curve. The basic idea for the development of this calibration method came from the key curve method. Unlike the key curve method, the calibration curve method curve-fits for an assumed deformation path during the crack growth process using the normalization scheme of dimensional analysis. This calibration curve contains all the information needed to generate both the fracture toughness value at crack initiation and the crack growth resistance curve for a growing crack. Using those calibration curves at different displacement rate loadings, the time function was developed to relate the viscoelastic quantities in the physical viscoelastic domain to the reference quantities in the reference elastic domain. The reference hyperbolic tangent calibration function was determined in the reference elastic domain using the same time function. A viscoelastic fracture mechanics theory was introduced. Extensive research efforts on fracture characterization of high molecular weight polymers have led to the development of a unique time-independent, elastic-like fracture characterizing parameter, J(sup *)(sub V)-integral, useful in describing the fracture behavior of nonlinear viscoelastic materials like ABS copolymer and modified PVC. DESIGN OF NEW POLYMERS TO IMPROVE RADIATION STABILITY OF PLASTIC SCINTILLATORS
N. Barashkov (Karpov, V. Y. Physical Chemistry Inst., Moscow, USSR.), N. Korotkikh (Karpov, V. Y. Physical Chemistry Inst., Moscow, USSR.), T. Novikova (Karpov, V. Y. Physical Chemistry Inst., Moscow, USSR.), F. Markley, A. Pla-Dalmau, G. Foster, and M. Rivard Nov. 1993 12 p
(Contract DE-AC02-76CH-03000)
(DE94-008220; FNAL-TM-1868) Avail: CASI HC A03/MF A01

Diffusion enhancers have been used to increase the radiation stability of scintillators. There is a danger that such additions will also allow the scintillation dyes to diffuse out of the matrix. Covalent bonding of the dyes into the matrix would eliminate any luminophore migration. We have demonstrated that dyes with vinyl and divinyl groups can be successfully bonded into a styrene matrix. Both primary and secondary luminophores have been bonded into the matrix and in several cases they have been compared with similar luminophores without the vinyl groups in otherwise identical compositions. In general the bonding does not greatly affect either the radiation stability of the composition or its light output, but is, therefore, proven to be an acceptable method of preventing luminophore migration. Scintillators with a base of aromatic or alicyclic epoxy resins have also been made with bonded luminophores. In these compositions, the bonding is accomplished by using luminophores with one or two amine groups or epoxy groups. When using the amines, they are first prereacted with the epoxy resin and the modified epoxy is then cured with hexahydrophthalic anhydride or trimethoxyboroxine. The emission and absorption spectra of many of these reactive luminophores are given, along with the light outputs and radiation stability of the resulting scintillators. DOE

IN-SITU TEM CRYSTALLIZATION OF ANORTHITE-GLASS FILMS ON (ALPHA)-AI2O3
M. P. Mallamaci (Minnesota Univ., Minneapolis.), C. B. Carter (Minnesota Univ., Minneapolis.), and J. Bentley 1993 6 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993 Sponsored in part by Oak Ridge Associated Universities, Inc., TN, and Martin Marietta Energy Systems, Inc., Oak Ridge, TN
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033; DE-FG02-92ER-45465)
(DE94-006317; CONF-931108-60) Avail: CASI HC A02/MF A01

Anorthite-glass films were grown by pulsed-laser deposition on single-crystal (alpha)-Al2O3 substrates which were pre-thinned to electron transparency. The glass films were crystallized in the transmission electron microscope (TEM), which allowed direct observation and video-recording of

the crystallization process. Crystallization of these films in the TEM resulted in the formation of hexagonal and orthorhombic anorthite. The orthorhombic phase was the predominant product of glass films grown at elevated substrate temperatures and displayed strong epitaxy with the underlying substrate. In contrast, the hexagonal phase was the major constituent of films grown at ambient substrate temperature and displayed no clear epitaxy with the substrate. The difference in degree of epitaxy and phase structure may be evidence of ordering at the original glass/oxide interface. DOE

ELASTIC MODULUS MEASUREMENTS OF LDEF GLASSES AND GLASS-CERAMICS USING A SPECKLE TECHNIQUE

D. E. Wiedlocher and D. L. Kinser 1992 7 p

(Contract NAS8-32695; NAG8-156; NASA Order L-17761-D)

(NASA-CR-195911; NAS 1.26:195911) Avail: CASI HC A02/MF A01

Elastic moduli of five glass types and the glass-ceramic Zerodur, exposed to a near-earth orbit environment on the Long Duration Exposure Facility (LDEF), were compared to that of unexposed samples. A double exposure speckle photography technique utilizing 633 nm laser light was used in the production of the speckle pattern. Subsequent illumination of a double exposed negative using the same wavelength radiation produces Young's fringes from which the in-plane displacements are measured. Stresses imposed by compressive loading produced measurable strains in the glasses and glass-ceramic. Author

Liquid/liquid miscibilities of four different 32 ISO VG polyolesters and one alkylbenzene at three concentrations have been determined with five refrigerant blends, including HC-290. A vapor lubricant equilibrium (VLE) viscosity reduction of 32 ISO VG mineral oil with HCFC-22 has been completed. Composite viscosity reduction information by the fractionate components from R-502 in 32 ISO VG mineral oil has been obtained from -10 C to 125 C isotherms. Vapor lubricant equilibrium (VLE) viscosity reduction for 32 ISO VG mixed acid polyolester with HFC-134a and HFC-143a has also been completed. Data is also presented for the viscosity reduction of 32 ISO VG branched acid polyolester by these same refrigerants. DOE

(AD-A276550) Avail: CASI HC A03/MF A01

The study to produce ultra-fine (less than 50 micrometers in diameter) lead zirconate titanate (PZT) ceramic fibers for passive damping application has been carried out under several aspects. Sol-gel chemistry was undertaken to produce stable spinnable sol, as well as high quality PZT fibers. Due to the extreme geometry of such fibers, special characterization and poling methods were established. Single fiber dielectric properties, polarization hysteresis, and mechanical properties have been measured. Several methods for applying optimum resistive coatings were also explored. The analytical model of passively damped polymer composites using resistively shunted piezoelectric fiber was further developed to predict the behavior of such composites. DTIC

TOUGHENING MECHANISMS IN THE HIGH STRAIN RATE DEFORMATION OF RUBBER-MODIFIED POLYMER GLASSES Ph.D. Thesis

Donald Joseph Buckley, Jr. 1993 386 p

Avail: Univ. Microfilms Order No. DA9318838

The deformation mechanisms operating in rubber-modified polymer glasses have been studied using real time small angle x ray scattering (RTSAXS) and transmission electron microscopy (TEM). Three series each of high impact polystyrenes (HIPS) and acrylonitrile butadiene styrenes (ABS) were examined under tensile impact and tensile creep loading at strain rates in the regime 0.01 to 50 /s while RTSAXS, x ray mass thickness, and lateral strain measurements were made. The plastic strains due to crazing, shear deformation, and cavitation were obtained at time resolutions of 1.6 to 10 ms as functions of the weight-averaged matrix molecular weight (M(sub w)), rubber phase microstructure, and strain rate. The HIPS series examined the effect of rubber particle size, internal particle structure, and rubber phase volume fraction on the deformation processes. Particle size and structure produced marginal effects on the distribution of the total strain among the various mechanisms and the impact toughness, but the toughness increased with increasing rubber volume fraction and decreasing interparticle spacing. Coarsening of the craze microstructure at high rubber weight fractions and low strain rates was attributed to stress-activated sorption of low molecular weight polybutadiene (PB) from the particles. The effects of matrix molecular weight, rubber weight fraction, and rubber particle size were examined in the three ABS series. No systematic change in the deformation behavior was observed in the M(sub w) and particle size series, but the shear strain, cavitation strain, and toughness all scaled with increasing rubber weight fraction. As in the HIPS series the craze microstructure coarsened with increase rubber content. The increase in toughness with volume fraction in both HIPS and ABS was attributed to increased crazing, cavitation, and shear deformation (in the ABS materials) with decreasing width of the interparticle ligaments of the matrix. The kinetics of the deformation mechanisms, equality of the crazing and cavitation strains, and TEM studies support a model of planar deformation zones consisting of interconnected crazes and voids, separated by elastically deformed material. Dissert. Abstr.

HIGH-TEMPERATURE DEFORMATION AND FRACTURE TOUGHNESS OF DUPLEX CERAMIC MICROSTRUCTURES Ph.D. Thesis

Jonathan David French 1993 176 p

Avail: Univ. Microfilms Order No. DA9325939

High temperature deformation and fracture toughness behavior of duplex ceramic microstructures were examined in this study to achieve a general understanding of the flow and fracture of this type of material. Two model systems were studied: Al2O3: c-ZrO2(Y) and Al2O3:YAG. A dual experimental approach was employed to study the equivolumetric compositions in relation to their single-phase constituents. Creep and fracture toughness at high temperatures were studied using indentation and more traditional techniques. In addition, the indentation crack length method for determining fracture toughness of brittle materials was evaluated at high temperatures. In general, the duplex microstructure exhibits a 'rule-of-mixtures' behavior, i.e., properties in between those of the single-phase constituents, for properties that are governed by the continuum nature of the material, such as tensile creep properties. A 'non-rule-of-mixtures' type behavior occurs for properties that have significant contributions from the interphase boundaries, such as the high temperature fracture. The tensile creep rates of the duplex microstructures were lower than their single-phase constituents. This was attributed to Y(sup +3) segregation to alumina grain boundaries that hinders the interface reaction believed to control diffusional creep in alumina. Accounting for the dopant effect, the tensile creep behavior of the duplex microstructures could be modeled using simple composite theory, applied to flow of two-phase materials. Indentation creep of the duplex microstructures relative to the single-phase constituents was system and temperature specific; however, under certain conditions similar trends were observed. The duplex microstructure of both systems exhibited higher fracture toughness values than their single-phase constituents at high temperatures, likely due to lower interfacial energies relative to the grain boundary energies of the single-phases. The indentation method was shown to be applicable to the measurement of high temperature fracture toughness, with some limitations. The measurement of high temperature creep properties with the indentation technique tests a range of stress and strain rates inaccessible to bulk techniques. Therefore, since different mechanisms are operative in the two techniques, correlation is limited. However, useful information can be obtained from this method as to the deformation behavior under the extremes

of stress, strain rate, and temperature, which may be applicable to machining or geological processes. Dissert. Abstr.

A FRACTURE MECHANICS METHODOLOGY FOR CHARACTERIZING THE PERFORMANCE OF FLAWED POLYMERIC DIELECTRIC MATERIALS Ph.D. Thesis
Scott Frederick Popelar 1993 113 p
Avail: Univ. Microfilms Order No. DA9325570

A fracture mechanics approach for quantifying slow crack growth in thin polyimide films and assessing their structural integrity and life expectancy is developed. The methodology and techniques presented in this document may also be applied to other polymeric materials. A test protocol for studying slow crack growth has been developed, along with an analysis model which deduces crack length histories from measured load-point displacements of single edge notched fracture specimens. From the crack length histories, the crack growth rate is correlated with the stress intensity factor. A series of room temperature tests were performed on the model materials 50HN, 100HN, 300H, and 500HN Kapton type polyimide film, and the corresponding crack growth rates were correlated with the stress intensity factor. A very strong dependence of the crack growth rate on the stress intensity factor is observed for all of the films. To a first approximation, the fracture process of these films can be taken to be governed by a critical value of the stress intensity factor. The fracture toughness of the films decreases with decreasing film thickness. A temperature-dependent shift factor was developed which consolidated creep compliance data at different temperatures into a single master curve at an arbitrary reference temperature. This same shift factor was used to shift crack growth rate and crack growth initiation time data gathered at elevated temperatures to a common reference temperature. Slow crack growth tests were performed on Kapton type 300H polyimide film at different combinations of temperature and relative humidity in order to investigate the influence of temperature and relative humidity on the fracture of Kapton film. The slow crack growth resistance was found to decrease with increasing temperature and humidity. The value of the initiation stress intensity factor decreased linearly with increasing humidity at the same temperature. It was found that temperature only influences the dry initiation stress intensity factor. Crack growth rate correlations were shifted to a reference temperature and relative humidity using a generalized form of the WLF equation. Dissert. Abstr.

CHEMICAL VAPOR DEPOSITION OF METAL NITRIDES, PHOSPHIDES, AND ARSENIDES
D. M. Hoffman 1994 2 p Prepared for Los Alamos National Lab., NM
(Contract W-7405-eng-36)
(DE94-008096; LA-Sub-94-41) Avail: CASI HC A01/MF A01

The author recently reported that dialkylamido complexes are promising precursors to nitride thin films. On this basis it was reasoned that transition metal and main group disilazide complexes in which the silicon has dialkylamido substituents are potential precursors to ternary silicon nitride films. Bulky disilazide ligands are known to stabilize main group and transition metal complexes with low coordination numbers. Reaction of dimethylamine with Cl3SiN(H)SiMe3 in hexane solution at 25 C gave the bulky disilazane ((Me2N)(sub 3)Si)N(H)SiMe3 (1) in 73 percent yield. Reaction of (1) with n-butyl lithium in benzene at 0 C produced ((Me2N)(sub 3)Si)N(Li)SiMe3 in 82 percent yield. LiN(Si(NMe2)(sub 3))(sub 2) was chemically prepared in 92 percent yield and was converted to the amine with 83 percent yield. The author examined the use of amido precursors for main group oxide thin films. Sn(NMe2)(sub 4) and Si(NMe2)(sub 4) react with oxygen in an atmospheric pressure chemical vapor deposition reactor to give SnO2 and SiO2 films, respectively. The films were deposited on quartz, silicon, and glass at substrate temperatures of 250 to 400 C. The results of the characterizations of the films and compounds are presented in this report. DOE

AZO POLYMERS FOR REVERSIBLE OPTICAL STORAGE. 4. COOPERATIVE MOTION OF RIGID GROUPS IN SEMICRYSTALLINE POLYMERS
A. Natansohn, P. Rochon, M. Pezolet, P. Audet, and D. Brown 1 Mar. 1994 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0615)
(AD-A277107; TR-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Polarized light induces a preferred orientation of azobenzene groups through photochemical trans-cis-trans processes. Stronger orientation tendencies exist if the azo-containing polymers are crystalline or liquid crystalline and the cooperative reorientation of nonactive mesogens of similar shape has been demonstrated. This paper shows that cooperative reorientation is a more general phenomenon and can take place even for a nonactive rigid group of a different shape which is bonded in the main chain while the azobenzene groups are in the side chains. Comparison is made between a disperse red containing amorphous azo polymer (pDR1A) and a disperse red 19 - containing semicrystalline azo polymer (pDR19T) with phenylene diacrylate (PD) groups within the main chain. Dichroic ratios are obtained from infrared and electronic spectra and are correlated with a writing / erasing / rewriting sequence performed with an argon laser. A maximum birefringence of 0.08 can be obtained on pDR1A, while on pDR19T the birefringence is 0.27 in similar conditions. This is the result of a combination of the semicrystallinity of pDR19T and of the cooperative orientation of PD groups along with the azobenzene groups. The drawback in terms of optical storage is the longer time required to write or erase. DTIC

RECENT DEVELOPMENTS IN POLYMERIC CHARGE TRANSFER COMPLEXES
A. Natansohn 1 Mar. 1994 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0615)
(AD-A277108; TR-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The recent literature on polymeric charge transfer complexes is reviewed with emphasis on the author's own work. After a definition of the area and a survey of investigations on the spatial arrangement of donor and acceptor sites in the solid state, a variety of applications of these complexes is presented. Electrically conductive polymers are excluded. These applications are: compatibilization of polymer blends, liquid crystalline supramolecular organization, new developments in photoconductivity, electroluminescence, nonlinear optical properties, photorefractivity, and reversible optical storage. REVERSIBLE OPTICAL STORAGE IN AZO POLYMERS
A. Natansohn and P. Rochon 1 Mar. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0615)
(AD-A277109; TR-9) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Amorphous high-Tg azobenzene containing polymers can be used as reversible information storage materials in the form of films. The procedure takes advantage of the photochemically activated trans-cis-trans isomerization of the azobenzene groups. The written information is stable below the polymer glass transition temperature. Writing and erasing can be performed up to 105 times on the same spot of the polymer film. The reorientation mechanism depends on the type of substituents bound to the azobenzene group, on the type of the neighboring group on the polymer chain, and on the tendency of the polymer to self-organize. The efficiency of the process depends on the maximum absorbance of the azobenzene group and can be tailored to reach unity. This property of azobenzene containing polymers can be used in optical and holographic memory, waveguides and sensors, and photonic devices. DTIC

PHOTOPOLYMERIZATION OF CYCLOHEXENE OXIDE: A VISIBLE LIGHT INITIATING SYSTEM AND MECHANISTIC INVESTIGATIONS
Yubai Bi and D. C. Neckers Feb. 1994 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1921)
(AD-A277110; TR-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A visible light initiator system for the photoinduced cationic polymerization of epoxides is reported. It uses free radical promoted cationic polymerization, the radical being generated from a visible light absorber. The developed system consists of an iodinated xanthene dye, a coinitiator and a diaryliodonium salt. Aromatic amines having low basicity and containing alpha-hydrogens are the preferred coinitiators for the polymerization of cyclohexene oxide. The system can efficiently photoinitiate the polymerization of certain cyclic ethers and can function at any wavelength of the visible spectrum depending on the dye's absorption spectrum and its oxidation/reduction potentials. Studies on photochemical reactions between each two of the three components and characterization of the polymer formed from cyclohexene oxide indicate that both the oxidative bleaching of the dye by the diaryliodonium salt and the reductive bleaching of the dye by the aromatic amine contribute to alpha amino radical formation and oxidation of the alpha amino radicals by diaryliodonium salts produces alpha-aminocarbocations which initiate the ring opening polymerization. Dye molecules are incorporated into the polymer in chain terminating processes. DTIC

MECHANICAL PROPERTIES OF ACRYLATE NETWORKS FORMED BY VISIBLE LASER-INDUCED POLYMERIZATION. 2. CONTROL OF THE MECHANICAL PROPERTIES

Afranio Torres-Filho and D. C. Neckers Feb. 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-1921)

(AD-A277111; TR-5) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The mechanical properties of some acrylate networks formed by visible laser-induced polymerization were studied as a function of the initial molecular composition of the reacting mixture. The study included, besides some changes in the monomer composition, the influence of the acidity of the medium when ionizable dyes were used as photoinitiators. It was also shown that the mechanical strength of the network polymers can be significantly improved by the addition of inorganic fillers which have been surface treated with silane coupling agents containing polymerizable groups, or by adding to the multifunctional acrylate monomers a solution containing a stronger preformed polymer. The work also describes different attempts to obtain an elastomeric material by copolymerizing a flexible acrylated oligomer with the networking monomers. DTIC

SOLVENT DIFFUSION COEFFICIENT CONCENTRATION DEPENDENCE IN POLYMER SOLUTIONS Technical Report, 1 Apr. 1993 - 15 Feb. 1994

R. A. Waggoner, Frank D. Blum, and J. M. MacElroy 15 Feb. 1994 36 p

(Contract N00014-91-J-1274)

(AD-A277023; UMR-FDB-33) Avail: CASI HC A03/MF A01

Self-diffusion coefficients of several different solvents in polystyrene as well as methyl methacrylate in poly(methyl methacrylate) have been determined at polymer concentrations from 0 to 50 wt% at 25 deg C. The solvents used for the polystyrene solutions were toluene, ethylbenzene, cumene, t-butyl acetate, chloroform, and methyl ethyl ketone. The diffusion data was used to evaluate several theories for the concentration dependence of the solvent diffusion coefficients, and in most cases the reduced diffusion coefficients, of solvents in polymer-solvent systems. In addition to the experimental data presented here, literature data for several systems were also used to test the models. The theories evaluated were based on widely different concepts including electrical conductivity, tortuosity, kinetic theory, and free-volume. The results indicate that the kinetic theory and free-volume approaches fit the data most consistently, with the kinetic theory approach preferred at lower polymer concentrations and the free-volume approach favored at higher polymer concentrations. (AD-A277261; TR-14) Avail: CASI HC A03

Nickel-catalyzed polymerization which employs the coupling of isomeric dichlorobenzophenones is described. The polymerization utilizes inexpensive readily available monomers, 4,4'-dichlorobenzophenone (4,4'-DCBP), and 2,5-dichlorobenzophenone (2,5-DCBP). The poly(4,4'-benzophenone) can be derivatized to be soluble during the synthesis by the use of a ketimine precursor that is subsequently hydrolyzed to give the target material. The polymerization of 2,5-dichlorobenzophenone yields a soluble derivative of poly(p-phenylene). The resulting polymers were characterized to confirm the composition, molar mass, and thermal properties. The Ni(O) catalyzed route proves to be facile and economically feasible and opens the way to a large variety of heterocyclic and phenyl-based homo- and copolymers. DTIC

A VISIBLE LIGHT INITIATING SYSTEM FOR FREE RADICAL PROMOTED CATIONIC POLYMERIZATION

Yubai Bi and D. C. Neckers 2 Feb. 1994 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-1921)

(AD-A277164; TR-3-ONR) Avail: CASI HC A04

A new visible light free radical promoted cation in chain polymerization is reported. The system is based on electron transfer photoreduction of xanthene dye triplets by aromatic amines possessing a hydrogen on the alpha carbon atom to the nitrogen. Subsequent deprotonation of the amine radical cation followed by onium salt oxidation leads to formation of an alpha-amino carbenium ion and the latter initiates polymerization. Critical to the success of the system are the basicity of the amine, the oxidation potential of the onium salt, and the presence or absence of nucleophilic centers in the monomer to be polymerized. The scope and details of the system are discussed in the publication. DTIC

Fluorescence depolarization studies of polysilane chains in solution have shown that energy transfer along the polymer chains occurs for only a very short time relative to the excited state lifetime and only over short distances before the excited states become trapped in long, low-energy segments. However, in solid films the authors have shown in previous work that excitons are highly mobile throughout their 600 ps lifetime at room temperature, presumably because energy transfer among neighboring, parallel chain segments becomes possible. In this paper the authors report that the exciton-exciton annihilation rate constant decreases by only a

factor of five between room temperature and 12 K, showing that the excitons do not become trapped even at low temperatures. DOE

We have investigated the densification behavior of sol-gel zirconia films resulting from ion irradiation. Three sets of films were implanted with neon, krypton, or xenon. The ion energies were chosen to yield approximately constant energy loss through the film, and the doses were chosen to yield similar nuclear energy deposition. Ion irradiation of the sol-gel films resulted in carbon and hydrogen loss as indicated by Rutherford backscattering spectrometry and forward recoil energy spectroscopy. Although the densification was hypothesized to result from target atom displacement, the observed densification exhibits a stronger dependence on electronic energy deposition. DOE

Important glass-water interactions are poorly understood for borosilicate glass radioactive waste forms. Preliminary results show that glass durability is dependent on reactions occurring at the glass-solution interface. CSG glass (18.2 wt. % Na2O, 5.97 wt. % CaO, 11.68 wt. % Al2O3, 8.43 wt. % B2O3, and 55.73 wt. % SiO2 dissolution and net surface H(sup +) and OH(sup (minus)) adsorption are minimal at near neutral pH. In the acid and alkaline pH regions, CSG glass dissolution rates are proportional to H(+) (sub adsorbed)(sup 2) and OH(-)(sub adsorbed)(sup 0.8), respectively. In contrast, silica gel dissolution and net H(+) and OH(-) adsorption are minimal and independent of pH in acid to neutral solutions. In the alkaline pH region, silica gel dissolution is proportional to OH(-)(sub adsorbed)(sup 0.9)(sub adsorbed). Although Na adsorption is significant for CSG glass and silica gel in the alkaline pH regions, it is not clear if it enhances dissolution, or is an artifact of depolymerization of the framework bonds. STATUS OF DEVELOPING A MULTIFUNCTIONAL AVIATION GREASE Final Report
In-Sik Rhee Jan. 1994 29 p
(AD-A276755; BRDEC-2546) Avail: CASI HC A03/MF A01

A program has been initiated to develop a new multifunctional helicopter grease. The purpose for the development of this new grease is to provide a product having significantly improved performance, reduce the overall logistics and supply burdens, reduce procurement costs, and control the continuing increase in proliferation of proprietary non-standard products. The effort during FY-91 - FY-92 was devoted to determine the preliminary target requirements and to formulate the experimental grease. In these efforts, the preliminary target requirements were developed based on what is believed to be achievable with current technology versus projected system requirements. Based on these preliminary target requirements, the experimental greases were formulated using an advanced lithium complex technology as thickener and a mix polyalphaolefin (PAO) synthetic base oil, a small amount of high viscosity mineral oils, and various additives. On the basis of the work completed to date, the experimental greases were very close to meeting the preliminary target requirements and are promising as the candidate aviation greases. DTIC

NMR STUDIES OF ORGANIC THIN FILMS Annual Report, 1 Jan. 1993 - 28 Feb. 1994
Frank D. Blum 28 Feb. 1994 73 p
(Contract N00014-91-J-1274)
(AD-A276953; UMR-FDB-34) Avail: CASI HC A04/MF A01

A review of the literature on NMR studies of thin organic films is given with 212 references. Special focus is given to the following: (1) polymers at interfaces including: solid-liquid, elastomer-solid, solid-gas, and solid-solid systems; and (2) surface active phases which were bonded and non-bonded. MULTIFUNCTIONAL MACROMOLECULES Final Report, 1 Jul. 1991 - 31 Jul. 1993
A. J. East, M. J. Sansone, and T. Findakly Oct. 1993 174 p
(Contract F49620-91-C-0062)
(AD-A277347; AFOSR-94-0082TR) Avail: CASI HC A08/MF A02

While numerous photorefractive polymers were synthesized by the incorporation of NLO chromophores and photoconductive components as side chains on a backbone, the most significant photorefractive behavior demonstration under this project was made in an electrooptic aminonitrostilbene methacrylate copolymer (P2ANS/MMA) without the addition of photoconductive compounds. By four wave mixing, photorefractive gratings were written in P2ANS/MMA using s-polarized and p-polarized writing beams and probed using orthogonally polarized probe beams. With probe beam orthogonally polarized to the write beams, well behaved, field dependent, stable responses ascribed to the photorefractive effect were observed. Diffraction efficiencies of 10(exp -4) to 10(exp -5) were obtained in 8 micrometer thick films under an applied field of 50 V/micrometer with response times of 1.5 to 2 minutes. Increasing the sample thickness to 100 micrometers is projected to result in a diffraction efficiency of 1 to 3 percent. DTIC

INFLUENCE OF TRACE COMPONENTS ON THE VISCOELASTIC PROPERTIES OF A POLYMER SOLUTION Final Report, Oct. 1986 - Feb. 1989
Seok H. Hong and Wendel J. Shuely Aug. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277171; ERDEC-TR-086) Avail: CASI HC A03

Research on characterization of viscoelastic properties of ultrahigh molecular weight polymer solutions led to the discovery of variations in rheological properties combined with variable dissolution behavior for certain polymer-liquid systems. The reference solutions exhibited extreme intra sample variations; therefore, the influence of processing and trace impurities on rheological property variance was studied. Measurements of first normal stress difference, apparent viscosity, and dynamic viscoelastic properties were performed as a function of controlled addition of components with

specific molecular interactions with polymers or solvents (e.g., various salts, surfactant, and chelating reagents). In addition, processing treatments such as filtration and centrifugation were applied and their influence on rheological properties of the polymer solution was determined. DTIC

DYNAMICS OF BLOCK POLY(STYRENE-CO-VINYLPYRIDINE) (SVP) IN SOLUTION AND ON SILICA
Frank D. Blum, M. Xie, B. R. Sinha, and F. C. Schwab 1 Mar. 1994 4 p
(Contract N00014-91-J-1274)
(AD-A277139; UMR-FDB-35) Avail: CASI HC A01/MF A01

Deuterium NMR relaxation measurements have been used to probe the dynamics of specifically labelled poly(styrene-co-vinyl pyridine) in solution and on silica. Of particular interest in this study was the comparison of the dynamics of the adsorbed polymers on silica with those of the block copolymer and homopolymer in solution. We found that in toluene, the styrene segments on the surface-bound polymer had enhanced mobility over that in toluene solution. This enhanced mobility does not extend to the other solvent systems tested (CCl4 and CCl4/CH3OH). For the latter systems, the styrene mobility on the surface bound-polymer was lower than those of the corresponding solutions, as expected. Thus, we conclude that this enhanced mobility probably occurs only in the presence of thermodynamically good solvents for styrene. A comparison of lower molecular weight (10 kg/mol) block copolymer and styrene homopolymer were also made in toluene. These results were interpreted through the use of the Hall-Helfand model for chain dynamics as indicating limited aggregation of the block copolymer in solution. DTIC

COMPATIBILITY STUDIES OF SOME AZO POLYMER BLENDS
Shuang Xie, Almeria Natansohn, and Paul Rochon 1 Mar. 1994 6 p
(AD-A277141; TR-10) Avail: CASI HC A02/MF A01

Azo polymers have many special properties. In the search for new materials for optical applications, such as reversible optical storage and nonlinear optical devices, azo polymers have attracted much attention. Polymers with low azo concentrations are particularly useful. The writing and erasing efficiency depends on the energy input from the irradiation light during the process. In principle, lower energies would be required to induce local variations of optical properties in polymers with low azo concentrations. DTIC

PROCESSING AND CHARACTERIZATION OF FUNCTIONALLY GRADIENT CERAMIC MATERIALS Final Report
M. E. ODay, L. C. Sengupta, E. Ngo, S. Stowell, and R. Lancto Feb. 1994 19 p
(AD-A277154; ARL-TR-337) Avail: CASI HC A03/MF A01

Tape casting of ceramic materials offers the flexibility of gradually altering the electronic or structural properties of two dissimilar systems in order to improve their compatibility. This research outlines the processing and fabrication of two systems-of functionally gradient materials. The systems are both electronic ceramic composites consisting Ba(1-x)Sr(x)TiO3 (BSTO) and alumina or a second oxide additive. These composites would be used in phased array antenna systems, therefore, the electronic properties of the material have specific requirements in the microwave frequency regions. The composition of the tapes are varied to provide a graded dielectric constant, which gradually increases from that of air (dielectric constant = 1) to that of the ceramic (dielectric constant = 1500). This allows maximum penetration of incident microwave radiation as well as minimum energy dissipation and insertion loss into the entire phase shifting device. DTIC

INTRAMOLECULAR CHARGE TRANSFER COMPLEXES AS FLUORESCENCE PROBES FOR UV AND VISIBLE LIGHT INDUCED ACRYLATE POLYMERIZATION
Jiancheng Song, Afranio Torres-Filho, and D. C. Neckers Feb. 1994 8 p
(Contract N00014-91-J-1921)
(AD-A277129; TR-4) Avail: CASI HC A02/MF A01

Intramolecular charge transfer complexes (ICTC) of derivatives of DANSYL AMIDE such as 1,5-DASB and 2,5-DASB, were used as fluorescence probes for cure monitoring of photocurable polymer systems. This technique is based upon the difference in fluorescence intensity from the parallel and perpendicular conformations of the excited state of the complex and is based on the dependence of the relative population of each conformation on the microviscosity of the system. As the curing reaction proceeds, the steady state fluorescence emission spectra of the probes were all found to exhibit hypsochromic spectral shifts due to the increase in matrix microviscosity. A linear correlation between the fluorescence intensity ratios and the extent of polymerization, measured by transmission FTIR spectrometry, was obtained for different types of acrylated polymers, cured with UV or visible (VIS) initiators. EFFECT OF SURFACE FORCES ON THE RHEOLOGY OF PARTICLE-LIQUID SYSTEMS AND THE CONSOLIDATION OF CERAMIC POWDERS Annual Report, 1 Feb. 1993 - 31 Jan. 1994
Fred F. Lange 31 Jan. 1994 81 p
(Contract N00014-90-J-1441)
(AD-A277092; TR-8; TR-9; TR-10; TR-11; TR-12) Avail: CASI HC A05/MF A01

More reliable ceramics require improved processing reliability. Heterogeneities bought with powders and those inadvertently introduced during processing as well as non-uniform and undefined phase distributions contribute to unreliable processing. Colloidal powder treatments can eliminate many heterogeneities and ensure more uniform phase distributions. To ensure that new heterogeneities are not introduced, colloidally treated powders must be piped, as slurries, directly to a die cavity. Slurry consolidation methods based on particle partitioning, e.g., pressure filtration and centrifugation are emphasized in this review. Interparticle potentials play a dominant role in governing the slurry viscosity, maximum particle packing density, and the rheology of the consolidate body. These roles will be reviewed with the objective to understand how damage free bodies can be consolidate from slurries to increase the structural reliability of ceramics and their composites. DTIC

PRESSURELESS SINTERING OF CERAMIC COMPOSITES Final Report
Martin W. Weiser 17 Jan. 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0265-90)
(AD-A277274; AFOSR-94-0056TR) Avail: CASI HC A04

This project examined the pressureless sintering and densification

behavior of model ceramic composites. The effect of inclusion aspect ratio on densification was studied using SiC whiskers and fibers in an Al2O3 matrix. Composites had maximum sintered density when made from fibers with aspect ratios around ten. This peak in the density is a result of the density of short aspect composites being inhibited by inclusion size considerations while long aspect composites are prevented from densifying by percolation related effects. How inhomogeneous inclusion distribution affects densification was studied using SiC(sub p)/Al2O3 composites. Three different types of inhomogeneity known as concentration, amplitude, and size were investigated. The sintered density was maximized at moderate levels of inclusion inhomogeneity. We also found that various salts were effective coagulating agents for slip casting Al2O3/ZrO2 composites. The drying of composites found that percolation limits the green density of particulate composites. The fracture toughness of Mn-Zn ferrites was increased from 0.9 to 2.8 MPa square root of m by addition of 25 volume percent partially stabilized ZrO2. Transient liquid phase sintering of composites is not an effective densification method. DTIC

ROBOTIC WELD OVERLAY COATINGS FOR EROSION CONTROL
B. F. Levin, J. N. DuPont, and A. R. Marder 20 Oct. 1993 57 p
(Contract DE-FG22-92PC-92542)
(DE94-008004; DOE/PC-92542/T4) Avail: CASI HC A04/MF A01

In the previous period of work, twelve overlay hardfacing alloys were selected for erosion testing based upon a literature review. All twelve coatings were deposited on 1018 steel substrates using the plasma arc welding process. Ten samples from each coating were prepared for erosion testing. The coating deposition and sample preparation procedures were described in the previous quarterly report. During the past quarter, all the coatings were erosion tested at 400 C. The erosion resistance of each coating was evaluated by determining the steady state erosion rate. In addition, the microstructure of each coating was characterized before and after the erosion tests. This progress report describes the erosion test results and coating microstructures. Also, a preliminary analysis on the relationships, between weld overlay coating hardness, microstructure, and erosion resistance will be discussed. DOE

LUBRICATION WITH BINARY MIXTURES: LIQUID-LIQUID EMULSION IN ELASTOHYDRODYNAMICS AND METAL FORMING Ph.D. Thesis
Songhao Wang 1992 155 p
Avail: Univ. Microfilms Order No. DA9318009

In this work we first investigate the lubrication of an EHD conjunction with binary mixtures of mineral oil and water, for small droplet size of the dispersed phase. Our emulsified lubricant is a homogeneous isotropic continuum of two components, and we employ the extended Reynolds equations of Al-Sharif et al. We find that the film thickness varies linearly with the logarithm of the droplet radius and also with the inlet volume fraction. Interestingly, with inlet volume fraction as low as 10 percent, oil pooling can occur, which agrees qualitatively with experimental observations. Second, based on the present Plasto-Hydrodynamic model of cold rolling lubrication, we examine the characteristics of lubrication with emulsion in this condition. We are able to predict several experimentally observed phenomena, e.g. an increase in the yield stress of the workpiece leads to increased volume fraction, i.e., enhanced pooling ahead of the conjunction. The effect of varying the parameters of the problem on pressure, film thickness, and volume fraction distributions are also discussed. Finally, for metal rolling lubrication, the influence of the elastic deformation at inlet zone is considered. The elasto-plastohydrodynamic lubrication model leads to more reasonable result than the plasto-hydrodynamic model.

JOINING OF SILICON NITRIDES USING OXYNITRIDE GLASSES
M. H. OBrien Mar. 1993 40 p
(Contract DE-AC07-76ID-01570)
(DE94-008517; EGG-SCM-10713) Avail: CASI HC A03/MF A01

This report presents a study on commercial silicon nitrides that were successfully joined using oxynitride glasses. Sintered silicon nitride was joined by either closed or glass-filled joints. Glass-filled joints were successfully used on hot-pressed silicon nitrides and were comparable in fast fracture strength to unjoined silicon nitrides up to approximately 1000C. Above that temperature, strengths decreased rapidly and glass flow failure began. The study observed that time-dependent failure currently limits the service temperatures of glass-filled joints. Creep failure occurred in excess of 1000C. Between 900 and 1000C, slow crack growth failure was observed. Cavitation (or viscous deformation) was the rate-controlling mechanism of slow crack growth. DOE

COMPATIBILITY OF REFRIGERANTS AND LUBRICANTS WITH ELASTOMERS
G. R. Hamed, R. H. Seiple, and Orawan Taikum Jan. 1994 529 p
(Contract DE-FG02-91CE-23810)
(DE94-008552; DOE/CE-23810/14) Avail: CASI HC A23/MF A04

The information contained in this report is designed to assist the air-conditioning and refrigeration industry in the selection of suitable elastomeric gasket and seal materials that will prove useful in various refrigerant and refrigeration lubricant environments. In part 1 of the program the swell behavior in the test fluids has been determined using weight and in situ diameter measurements for the refrigerants and weight, diameter and thickness measurements for the lubricants. Weight and diameter measurements are repeated after 2 and 24 hours for samples removed from the refrigerant test fluids and 24 hours after removal from the lubricants. Part 2 of the testing program includes the evaluation of tensile strength, hardness, weight, and dimensional changes after immersion aging in refrigerant/lubricant mixtures of selected elastomer formulations at elevated temperature and pressure. NEW DEVELOPMENTS IN SECOND-ORDER NONLINEAR OPTICAL POLYMERIC MATERIALS Technical Report, 1 Jun. 1993 - 31 May 1994
S. K. Tripathy, W. K. Kim, B. Bihari, D. W. Cheong, and J. Kumar 17 Mar. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1148)
(AD-A277409; TR-94-11) Avail: CASI HC A03

Second harmonic generation (SHG) from the spin coated films of an asymmetrically substituted polydiacetylene, namely poly((8-butoxy cardonyl) methyl urethanyl) 1-(5-pyrimidyl)- octa-1,3- diyne (BPOD), is reported. The macromolecules assemble to produce the organization responsible for SHG without recourse to poling. d33 of the spin coated film (0.19 to 0.31 micrometers thickness) are between 0.78 to 0.88 pm/V without absorption correction and 3.32 to 5.57 pm/V after correction. Angular and polarization dependence study of the second harmonic response suggests that the film has in-plane isotropy as a whole and the net dipole is nearly perpendicular to the film surface. Spontaneous orientation of the polymer chains during the film formation seems to be responsible for the noncentrosymmetric alignment of the polymer. SHG from the Langmuir-Blodgett films are also reported. DTIC

(Contract N00014-90-J-1148)
(AD-A277410; TR-94-07) Avail: CASI HC A02/MF A01

Nonlinear optical (NLO) polymers have shown increased potential in practical applications, such as frequency doubling and electro-optic modulation, due to their large nonlinearity and ease of processing. A practical NLO polymer will need to possess large second-order nonlinearity, excellent temporal stability at elevated temperatures, and low optical loss. A number of NLO polymers have been developed to exhibit large second-order NLO coefficients comparable to those of the inorganic NLO materials which are currently in use in devices. However, the major drawback of NLO polymers is the decay of their electric field induced second-order optical nonlinearities. This decay is a result of the relaxation of the NLO chromophores from the induced noncentrosymmetric alignment to a random configuration. Numerous efforts have been made to minimize this decay through different approaches. Recently, we have reported on an approach to stable second-order NLO polymers using an interpenetrating polymer network (IPN) structure. This IPN system, with the hybrid properties of a high glass transition temperature

(T(sub g)), an extensively crosslinked network, and permanent entanglements, exhibited excellent temporal stability at elevated temperatures. In this report, a new IPN system, modified from the one reported earlier, with higher degree of crosslinking density and larger NLO chromophore density is investigated. DTIC

NONLINEAR OPTICAL POLYMERS DERIVED FROM ORGANIC/INORGANIC COMPOSITES Technical Report, 1 Jun. 1993 - 31 May 1994
S. K. Tripathy, J. Kumar, J. I. Chen, S. Marturunkakul, and R. J. Jeng 18 Mar. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1148)
(AD-A277408; TR-94-10) Avail: CASI HC A03

A general approach to the development of multicomponent multifunctional stable NLO materials based on sol-gel reactions has been discussed. We have shown that these second order NLO organic/inorganic composites exhibit excellent room temperature stability of the second order optical nonlinearity. The final structure is an orientationally ordered organic/inorganic network. After an initial decay, excellent long term stability at elevated temperatures, ranging from 100 to 120 C, is observed for a number of different systems. The second order optical nonlinearities are reasonably large for practical device considerations. DTIC

Data presented in this report represent an intense effort to improve processing methods, testing methods, and general mechanical properties of candidate ceramics for use in advanced heat engines. Materials discussed include GN-10, GS-44, GTE PY6, NT-154, NT-164, sintered reaction-bonded silicon nitrides, silicon nitride combined with rare-earth oxides, NT-230, Hexoloy SX-G1, Dow Corning's beta-Si3N4, and a few whisker-reinforced ceramic composites. Information in this report was taken from the project's semiannual and bimonthly progress reports and from final reports summarizing the results of individual studies. Test results are presented in tabular form and in graphs. The objective of this report is to make available the test results from these studies but not to draw conclusions from those data. DOE

COMPOSITIONS AND CHEMICAL BONDING IN CERAMICS BY QUANTITATIVE ELECTRON ENERGY-LOSS SPECTROMETRY
J. Bentley, L. L. Horton, C. J. McHargue, S. McKernan, and C. B. Carter 1993 6 p Presented at the Materials Research Society Meeting, Pittsburgh, PA, 29 Nov. - 3 Dec. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE94-007208; CONF-9311153-2) Avail: CASI HC A02

Quantitative electron energy-loss spectrometry was applied to a range of ceramic materials at a spatial resolution of less than 5 nm. Analysis of Fe L(sub 23) white lines indicated a low-spin state with a charge transfer of approximately 1.5 electrons/atom onto the Fe atoms implanted into (amorphized) silicon carbide. Gradients of 2 to 5% in the Co:O stoichiometry were measured across 100-nm-thick Co3O4 layers in an oxidized directionally solidified CoO-ZrO2 eutectic, with the highest O levels near the ZrO2. The energy-loss near-edge structures were dramatically different for the two cobalt oxides; those for CO3O4 have been incorrectly ascribed to CoO in the published literature. Kinetically stabilized solid solubility occurred in an AlN-SiC film grown by low-temperature molecular beam epitaxy (MBE) on alpha(6H)-SiC, and no detectable interdiffusion occurred in couples of MBE-grown AlN on SiC following annealing at up to 1750C. In diffusion couples of polycrystalline AlN on SiC, interfacial 8H sialon (aluminum oxy-nitride) and pockets of Si3N4-rich beta(prime) sialon in the SiC were detected. DOE

Phosphazene-based, inorganic-polymer composites were produced and evaluated as potential engineering materials. The thermal, chemical, and mechanical properties of several different composites made from one polymer formulation were measured. The measured properties are very good, and the composites show excellent promise for structural applications in harsh environments. Chopped fiberglass, mineral, cellulose, and woodflour filled composites were tested. Chopped fiberglass filled composites showed the best overall properties. The phosphazene composites are very hard and rigid. They have low dielectric constants and typical linear thermal expansion coefficients for polymers. In most cases, the phosphazene materials performed as well or better than analogous, commercially available, filled phenolic composites. After 3 to 5 weeks of exposure, both the phosphazene and phenolics were degraded to aqueous bases and acids. The glass filled phosphazene samples were least affected. DOE

FABRICATION, PHASE TRANSFORMATION STUDIES AND CHARACTERIZATION OF SiC-AlN-Al2OC CERAMICS
A. V. Virkar, Qiang Tian, and Jong Chen 1993 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-FG03-93ER-45482)
(DE94-008587; DOE/ER-45482/1) Avail: Issuing Activity (Department of Energy (DOE))

During the first year of the grant, research was conducted in three areas. Research underway on the effect of coherency strains on phase separation in the AlN-Al2OC was written into a manuscript. A study of interdiffusion in the SiC-AlN system was initiated. Work on theoretical analysis for determination of symmetry of morphology of phase separation in a hexagonal system was initiated. A brief description of the progress during the past six months is given, followed by a summary of work planned for next year. DOE

STRUCTURE-PROPERTY RELATIONSHIPS OF CARBON AEROGELS
R. W. Pekala, C. T. Alviso, and F. M. Kong Dec. 1993 4 p Presented at the 3rd Pacific Polymer Conference, Gold Coast, Australia Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-007120; UCRL-JC-114787; CONF-931255-1) Avail: CASI HC A01

Of the organic reactions in sol-gel polymerizations, the most studied reaction is the aqueous polycondensation of resorcinol with formaldehyde; the resulting crosslinked gels are supercritically dried from CO2 to give resorcinol-formaldehyde (RF) aerogels. These aerogels can be pyrolyzed to form vitreous carbon monoliths with black color, high porosity, ultrafine cell/pore size, high surface area, and interconnected particles of the organic precursor. The structure and properties of the carbon aerogels depend on R/C (resorcinol/catalyst) ratio of starting solution, pyrolysis temperature, and chemical activation. Each variable is discussed. Carbon aerogels provide an almost ideal electrode material (in double-layer capacitors) owing to low electrical resistivity (less than 40 mohm-cm), controllable pore size distribution (5-500 angstrom), and high volumetric surface areas (app ximately 500 m(exp 2)/cm(exp 3)). AN INVESTIGATION OF THE RADIOLYTIC STABILITY OF A RESORCINOL-FORMALDEHYDE ION EXCHANGE RESIN
C. L. Crawford, N. E. Bibler, and J. P. Bibler 1993 26 p Presented at the Waste Management 1994, Tucson, AZ, 27 Feb. - 3 Mar. 1994
(Contract DE-AC09-89SR-18035)
(DE94-007971; WSRC-MS-93-550; CONF-940225-67) Avail: CASI HC A03/MF A01

Radiolytic stability of a resorcinol-formaldehyde polycondensation type cation exchange resin was investigated for up to 1 x 10(exp 9) rads total dose. The resorcinol-formaldehyde resin is a resin that has potential cesium decontamination applications at Pacific Northwest and Savannah River. We have determined both radiation and storage effects on performance of the resin using 101-AW Hanford simulant and ASTM type 1 water. Distribution coefficient determinations, total carbon analysis, and physical observations lead us to conclude that radiation up to 1 x 10(exp 8) rads does not significantly affect the performance of the resin. The resin is more stable to radiation in water than in 101-AW Hanford simulant. Also radiation or storage does not affect the thermal stability of the resin. Gas production rates for several resin slurries increased in the order of resin/101-AW Hanford simulant, resin/ASTM water, and resin/0.5 M HNO3. H2 is produced from radiolysis of resin in 101-AW Hanford simulant with a G value of G(H2) of 0.11 +/- 0.02 molecules/100 eV and in 0.5 M HNO3 with a G value of G(H2) of 0.27 +/- 0.02 molecules/100 eV. MICROSTRUCTURE OF COPOLYMERS CONTAINING DISPERSE RED 1 AND METHYL METHACRYLATE
Shuang Xie, Almeria Natansohn, and Paul Rochon 1 Mar. 1994 7 p
(AD-A277140; TR-11) Avail: CASI HC A02/MF A01

Two series of copolymers containing disperse red 1 and methyl methacrylate have been synthesized: poly(4'- (((2- (acryloyloxy)ethyl) ethyl) amino) -4 - nitroazobenzene - co-methylmethacrylate) (poly - (DRIA-co-MMA)) and poly(4'- (((2- (methacryloyloxy) ethyl) ethyl) amino) -4- nitroazobenzene -co-methyl methacrylate) (poly(DR1M -co-MMA)). The sequence distribution of the two series of copolymers is calculated on the basis of the estimated reactivity ratio values and analyzed by 13C-NMR spectroscopy. Methylmethacrylate centered triad MMD, DMD, and MMM and disperse red 1 centered triad DDD fractions are derived from the alpha-methyl carbon of MMA and carbonyl carbon in poly (DR1A-co-MMA). Good agreement is found between the spectral deconvolution results and the calculated results. Polymer tacticity is analyzed with the main chain quaternary carbon and carbonyl carbon in poly(DR1M-co-MMA). No spectral sequence distribution information is available for this series. DTIC

TEMPERATURE-HUMIDITY-BIAS AGING TECHNIQUE TO IDENTIFY DEFECTIVE SURFACE MOUNT CAPACITORS
R. Chanchani 1994 11 p Presented at the 14th Capacitor and Resistor Technology Symposium, Jupiter Beach, FL, 21-24 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005354; SAND-94-0054C; CONF-940337-2) Avail: CASI HC A03/MF A01

Ceramic chip capacitors can potentially crack due to thermal stresses in a surface mount assembly process. The electrical performance of the cracked capacitors will degrade with time, and they will prematurely short. In high reliability applications, the cracked capacitors must be identified and eliminated. We have developed and demonstrated the temperature-humidity-bias (THB) aging technique to identify cracked capacitors. The initial phase of the study involved setting up automated test equipment to monitor 100 surface mounted capacitors at 85% relative humidity, 85 degrees C with 50 volts dc bias. The capacitors subjected to severe thermal shock were aged along with control samples. Failure mode analysis was done on the failed capacitors. The capacitors with surface cracks short-out within the first 8 hours of aging, whereas the capacitors that failed after a longer aging time (8 to 1000 hours) had a shorting path in an internal void. Internal voids are typical defects introduced during manufacturing of multilayer ceramic (MLC) capacitors. In the second phase of the study, we used the THB aging technique to study the effect of surface mount processes on capacitor cracking and, thus the reliability. The surface mount processes studied were vapor phase, infrared (IR) and convection belt reflow soldering. The results showed that 6.3% of vapor phase soldered capacitors, and 1.25% of the IR and convection belt soldered capacitors had cracks. In all capacitors, regardless of the solder process used, an additional 3 to 4% of the capacitors failed due to a shorting path in the internal void. The results of this study confirm that this technique can be used to screen cracked capacitors and compare different solder and manufacturing processes. DOE

CONJUGATED POLYMER FLUORESCENCE: INTERPLAY OF CORRELATIONS AND ALTERNATION
Z. G. Soos (Princeton Univ., NJ.), D. S. Galvao (Bell Communications Research, Inc., Red Bank, NJ.), S. Etemad (Bell Communications Research, Inc., Red Bank, NJ.), and R. G. Kepler 1993 6 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-005587; SAND-93-1587C; CONF-931108-89) Avail: CASI HC A02/MF A01

Conjugated polymers can have high conductivity on doping, large nonlinear optical response in semiconducting state, and be used as LED's. These polymers include polyactylene, polydiacetylenes, polysilanes, polythiophene, poly-p- phenylenevinylene. Polymer fluorescence is related to the lowest singlet excited state S(sub 1). Polymer and oligomer data are shown for the excitation energy ratio of the two-photon and one-photon gaps. There is a ratio crossover with increasing e-e correlations in any centrosymmetri chain with an insulating ground state. The pi-conjugated polymers present various band gaps at constant correlations, and single-particle gaps can be related to the structure. The nature of the lowest singlet excited state depends sensitively on both correlations and alternation. DOE

MASS-LOADED COATING FOR REDUCING THE RESONANT FREQUENCY OF A CERAMIC DISC Patent Application
Patrick Monahan, inventor (to Navy) 27 Sep. 1993 10 p
(AD-D016095; US-Patent-Appl-SN-127178) Avail: CASI HC A02/MF A01

A mass-loaded coating includes a predetermined mass of powdered

lead which is mixed preferably in a ratio of 3:1 with a liquid polyurethane primer. When painted onto the surface of a disk or plate, the coating mass-loads the disc and lowers the resonant frequency of the disk without significantly increasing the physical dimensions of the disk. Thicker consistency adhesives, such as spreadable paste adhesives or thick putty-like adhesives may be substituted for mass-loading objects having irregular surface textures or complex shapes. DTIC

MICROANALYTICAL STUDY OF DEFECT FORMATION IN THIN BISMUTH STRONTIUM CALCIUM COPPER OXIDE FILMS
R. H. Howell, A. Chaiken, and R. G. Musket et al Jan. 1994 12 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-008217; UCRL-JC-115842; CONF-940142-25) Avail: Issuing Activity (Department of Energy (DOE))

Thin bismuth strontium calcium copper oxide (BSCCO) films and BSCCO/insulator/BSCCO trilayers have been prepared on SiTiO3 and MgO substrates by evaporation from elemental sources in an ozone atmosphere. Accurate control of the stoichiometry is achieved through monitoring of the atomic fluxes by use of in situ atomic absorption spectroscopy as well as by reflection high energy electron diffraction (RHEED). Nevertheless, nanometer-scale, second phase precipitates are sometimes observed. These defects and the flat regions around them have been probed by a variety of microanalytical techniques, including Rutherford backscattering spectroscopy (RBS), particle-induced x ray emission (PIXE), atomic force microscopy (AFM), microscopic secondary ion mass spectroscopy, and transmission electron microscopy (TEM). NUCLEATION AND GROWTH OF CUBIC BORON NITRIDE FILMS PRODUCED BY ION-ASSISTED PULSED LASER DEPOSITION
T. A. Friedmann, D. L. Medlin, P. B. Mirkarimi, K. F. McCarty, E. J. Klaus, D. R. Boehme, H. A. Johnsen, M. J. Mills, and D. K. Ottesen 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-007295; SAND-93-3872C; CONF-931108-85) Avail: CASI HC A02/MF A01

We are studying the boron nitride system using a pulsed excimer laser to ablate from hexagonal BN (cBN) targets to form cubic BN (cBN) films. We are depositing BN films on heated (25-800 C) Si (100) surfaces and are using a broad-beam ion source operated with Ar and N2 source gases to produce BN films with a high percentage of sp3-bonded cBN. In order to optimize growth and nucleation of cBN films, parametric studies of the growth parameters have been performed. The best films to date show greater than 85% sp3-bonded BN as determined from Fourier-transform infrared (FTIR) reflection spectroscopy. High resolution transmission electron microscopy (TEM) and selected area electron diffraction confirm the presence of cBN in these samples. The films are polycrystalline and show grain sizes up to 30--40 mn. We find from both the FTIR and TEM analyses that the cBN content in these films evolves with growth time. Initially, the films are deposited as hBN and the cBN nucleates on this hBN underlayer. Importantly, the position of the cBN IR phonon also changes with growth time. Initially this mode appears near 1130 cm(exp -1) and the position decreases with growth time to a constant value of 1085 cm(exp -1). Since in bulk cBN this IR mode appears at 1065 cm(exp -1), a large compressive stress induced by the ion bombardment is suggested. In addition, we report on the variation in cBN percentage with temperature. DOE

COMPILATION OF DIAMOND-LIKE CARBON PROPERTIES FOR BARRIERS AND HARD COATINGS
D. A. Outka, Wen L. Hsu, D. R. Boehme, N. Y. C. Yang, D. K. Ottesen, H. A. Johnsen, W. M. Clift, and T. J. Headley Feb. 1994 54 p
(Contract DE-AC04-76DR-00789)
(DE94-008231; SAND-94-8219) Avail: CASI HC A04/MF A01

Diamond-like carbon (DLC) is an amorphous form of carbon which resembles diamond in its hardness, lubricity, and interest for hardness, lubricity, and resistance to chemical attack. Such properties make DLC of use in barrier and hard coating technology. This report examines a variety of properties of DLC coatings which are relevant to its use as a protective coating. This includes examining substrates on which DLC coatings can be deposited; the resistance of DLC coatings to various chemical agents; adhesion of DLC coatings; and characterization of DLC coatings by electron microscopy, FTIR, sputter depth profiling, stress measurements, and nanoindentation. CHARACTERIZATION OF CROSSLINKED ELECTROOPTIC POLYIMIDES
M. B. Meinhardt, P. A. Cahill, C. H. Seager, A. J. Beuhler, D. A. Wargowski, K. D. Singer, T. C. Kowalczyk, and T. Z. Kosc 1993 7 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-007934; SAND-93-1752C; CONF-940142-23) Avail: CASI HC A02/MF A01

The electrooptical properties of Ultradel(trademark) 9000D polyimides doped with dyes DCM and DADC, a bis(carbazole) analog of DCM with improved thermal stability, are reported. Cure temperatures were restricted to 240C or less to minimize potential thermal degradation of these dyes. Low poling fields of 30 V/(mu)m were used in these experiments and yielded r(sub 13) coefficients in the 0.1-0.8 pm/V range. Photothermal deflection measurements of dye-doped Ultradel 9000D samples showed low optical absorption losses in systems cured at 175C, but losses exceeded 20 dB/cm in samples cured at 300C. DOE

METAL ION COMPLEXATION BY IONIZABLE CROWN ETHERS
R. A. Bartsch Jul. 1993 38 p
(Contract DE-FG05-88ER-13832)
(DE94-008301; DOE/ER-13832/36) Avail: CASI HC A03/MF A01

Cyclic and acyclic polyether compounds with pendent carboxylic acid, phosphonic acid monoethyl ester, sulfonic acid, phosphinic acid, and hydroxamic acid groups have been synthesized. The proton-ionizable polyethers can come with and without lipophilic groups. Two types of lipophilic di-ionizable lariat ethers have been prepared. Conformations of proton-ionizable lariat ethers have been probed. Competitive alkali metal cation transport by syn-(decyl)dibenzo- 16-crown-5-oxyacetic acid and lipophilic proton-ionizable dibenzo lariat ethers in polymer-supported liquid membranes was studied. Complexation of alkali metal cations with ionized lariat ethers was studied. Condensation polymerization of cyclic and acyclic dibenzo polyethers containing pendent mono-ionizable groups with formaldehyde produces novel ion exchange resins with both ion exchange sites for metal ion complexation and polyether binding sites for metal ion

recognition. Resins prepared from lariat ether dibenzo phosphonic acid monoethyl esters show strong sorption of divalent heavy metal cations with selectivity for Pb(2+). DOE

X RAY ABSORPTION STUDY OF PULSED LASER DEPOSITED BORON NITRIDE FILMS
A. Chaiken, L. J. Terminello, J. Wong, G. L. Doll, and T. Sato 2 Feb. 1994 8 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-48)
(DE94-008295; UCRL-JC-114133; CONF-931108-91) Avail: CASI HC A02/MF A01

B and N K-edge x-ray absorption spectroscopy measurements have been performed on three BN thin films grown on Si substrates using ion-assisted pulsed laser deposition. Comparison of the films' spectra to those of several single-phase BN powder standards shows that the films consist primarily of sp2 bonds. Other features in the films's spectra suggest the presence of secondary phases, possibly cubic or rhombohedral BN. Films grown at higher deposition rates and higher ion-beam voltages are found to be more disordered, in agreement with previous work. DOE

EFFECT OF ELEVATED TEMPERATURE AND CYCLIC LOADING ON PROPERTIES AND DAMAGE MODES IN CERAMIC COMPOSITES
K. L. Reifsnider, W. W. Stinchcomb, L. Oleksuk, S. S. Lee, and D. P. Stinton Nov. 1993 30 p Prepared in cooperation with Virginia Polytechnic Inst. and State Univ., Blacksburg, VA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-008736; ORNL/Sub-87-SA946/03; CCMS-93-18) Avail: CASI HC A03

This report discusses the results of a ongoing program of research concerned with the investigation of the effects of elevated temperature on the properties and performance of ceramic composites. The present report is concerned with just two aspects of the general program, the changes in properties and damage modes due to the effects of exposure of two ceramic composite systems to high temperature air and multiaxial loading. Two material systems and specimen configurations are discussed. Tubular specimens fabricated at the Oak Ridge National Laboratory using a SiC/SiC combination were tested quasi-statically at elevated temperatures. Changes in stiffness as a function of time and temperature were observed, and an SEM study revealed substantial differences in the microstructure associated with that exposure. Flat Nicalon/CAS-2 coupons were fabricated by the Corning Glass Company, subjected to elevated temperature soaks for various periods of time and temperature, and then tested monotonically and under cyclic loading. Changes in damage and failure modes were observed in that system, and a new surface damage mode on the fiber was discovered, possibly due to frictional sliding. The present report discusses the observations, interpretations, and some micromechanical modeling associated with these activities and discusses the consequences of these temperature effects on future 'designs' of material systems. MATERIALS DEVELOPMENT PROGRAM: CERAMIC TECHNOLOGY PROJECT BIBLIOGRAPHY, 1984-1992
Mar. 1994 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-009297; ORNL/M-3201) Avail: Issuing Activity (Department of Energy (DOE))

The Ceramic Technology for Advanced Heat Engines Project was begun in 1983 to meet the ceramic materials needs of the companion DOE automotive engine program, the Advanced Gas Turbine (AGT) project, and the Heavy Duty Transport (low-heat-rejection, heavy-duty diesel) project. The goal is to develop an industry technology base for reliable and cost effective ceramics for applications in advanced automotive gas turbine and diesel engines. Research areas were identified following extensive input from industry and academia. Majority of research is done by industry (60%); work is also done at colleges and universities, in-house, and at other national laboratories and government agencies. In the beginning, reliability of ceramic components was the key issue. The reliability issues have largely been met and, at the present time, cost is the driving issue, especially in light of the highly cost-sensitive automotive market. Emphasis of the program has now been shifted toward developing cost-effective ceramic components for high-performance engines in the near-term. This bibliography is a compilation of publications done in conjunction with the Ceramic Technology Project since its beginning. Citations were obtained from reports done by participants in the project. We have tried to limit citations to those published and easily located. The end date of 1992 was selected. DOE

CONVERSION OF POLYMERS OF METHYL- AND VINYLSILANE TO Si-C CERAMICS
Frances I. Hurwitz, Terrance A. Kacik, Xin-Ya Bu, John Masnovi, Paula J. Heimann, and Kassahun Beyene Apr. 1994 8 p Presented at the MRS Spring Meeting, San Francisco, CA, 4-8 Apr. 1994, sponsored by the Materials Research Society
(Contract NCC3-63; RTOP 505-63-51)
(NASA-TM-106554; E-8704; NAS 1.15:106554) Avail: CASI HC A02/MF A01

Poly(methylsilane) and poly(vinylsilane) were synthesized using a titanocene catalyst, and their pyrolytic conversion to ceramics was followed using a combination of thermal analysis and infrared spectroscopy. The two polymers have distinctly different backbone structures, as determined by Si NMR; methylsilane polymerizes to a polysilane, while vinylsilane polymers have predominately polycarbosilane backbone, with some polysilane structure as well. The pyrolysis path and char yield were dependent primarily on backbone structure, with little influence of polymer molecular weight. The majority of the weight loss on conversion occurs below 650 degrees C, although bond rearrangement continues to 1400 degrees C. Poly(vinylsilane) produced a C-rich Si-C ceramic in which the carbon was dispersed on a sufficiently fine level to show resistance to oxidation on heating in air to 1400 degrees C. Author

SILICON-BASED OPTOELECTRONIC MATERIALS SYMPOSIUM AND MATERIALS RESEARCH SOCIETY PROCEEDINGS, VOLUME 298 Final Report, 15 Jun. - 14 Dec. 1993
John Ballance 14 Dec. 1993 476 p Proceedings held in San Francisco, CA, 12-14 Apr. 1993
(Contract F49620-93-1-0383)
(AD-A277518; AFOSR-94-0041TR) Avail: CASI HC A21/MF A04

Although silicon is at the heart of the microelectronics revolution, its low optical efficiency has limited its use in optoelectronic applications. The potential significance of combining communications and display technology with microelectronics technology has generated considerable activity directed at developing a silicon-compatible optoelectronic material. The last few years have seen some interesting and potentially important advances in this area. Symposium B was organized as a forum for the various groups studying the physics, materials science, processing, and applications of silicon-based optoelectronic materials to present their most recent results in this rapidly growing field. Talks were organized into five basic areas: Si(1-x)Ge(x), rare earth-doped silicon (this session was organized jointly with symposium, E, Rare Earth Doped Semiconductors), silicon nanoparticles, porous silicon, and applications. Many of the key research groups in each of these areas were represented at the meeting. DTIC

PHASE BEHAVIOR, STRUCTURE, AND PROPERTIES OF MODEL BLOCK POLYMERS Final Report, 15 Apr. 1990 - 14 Oct. 1993
Frank S. Bates 14 Oct. 1993 15 p
(Grant AF-AFOSR-0207-90)
(AD-A277530; AFOSR-94-0094TR) Avail: CASI HC A03/MF A01

This project brought together three distinct experimental methods in an integrated investigation of the phase behavior, structure, and properties of block copolymers in the vicinity of the order-disorder transition. Anionic polymerization of polydiene diblock copolymers followed by catalytic hydrogenation was used to produce three classes of model saturated hydrocarbon materials. Dynamic mechanical spectroscopy and large amplitude dynamic shearing were employed to probe and manipulate,

respectively, the melt state microstructure. Small angle neutron scattering (SANS) experiments provided detailed information regarding the structure of the materials. A significant achievement during this work was the development of a dynamic shearing device that could be operated in situ with a SANS instrument. Together with the spectrum of materials produced, this combined scattering-rheology technique has led to a qualitative improvement in our understanding of block copolymer phase behavior and uncovered a rich polymorphism that is accompanied by dramatic variations in physical properties. Two new parameters have been shown to play a crucial role in determining block copolymer phase behavior. The degree of polymerization controls the extent of composition fluctuations which strongly affects the types of phases encountered near the order-disorder transition. Conformational asymmetry, which is controlled by the block volume and radius of gyration, leads to different phases on either side of the phase diagram. These effects have not been accounted for theoretically. DTIC

INTERPENETRATING POLYMER NETWORK ACOUSTIC DAMPING MATERIAL Patent
Usman A. Sorathia, inventor (to Navy), William L. Yeager, inventor (to Navy), and Timothy L. Dapp, inventor (to Navy) 17 Aug. 1993 5 p Filed 28 Aug. 1991
(AD-D016141; US-Patent-5,237,018; US-Patent-Appl-SN-751352;
US-Patent-Class-525-454) Avail: US Patent and Trademark Office

Improved acoustic damping materials comprise interpenetrating polymer networks having a soft polymer component and a hard polymer component. The soft polymer component, constituting from 75 to 95, preferably 90, percent by weight of the material, is made by polymerizing an aromatic diisocyanate with a polyalkylene ether glycol, and the hard polymer component is a vinyl ester polymer made by polymerization of the acrylate or methacrylate ester of the diglycidyl ether of a polyphenol. The curing of the mixture is carried out at room temperature in presence of a peroxide and an aromatic amine. The mixture of ingredients, while liquid, may be injected into mechanical devices, such as shafts of rotating equipment whose noise is to be dampened, and allowed to cure therein. DTIC

LOW LOSS SECOND-ORDER NONLINEAR OPTICAL POLYMERS BASED ON ALL ORGANIC SOL-GEL MATERIALS
R. J. Jeng, G. H. Hsiue, J. I. Chen, S. Marturunkakul, and L. Li 16 Mar. 1994 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1148)
(AD-A277482; TR-94-06-ONR; Rept-1148-94-06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A new class of all organic sol-gel second-order nonlinear optical (NLO) materials based on hexa(methoxymethyl) melamine (HMM) has been developed. Two NLO active chromophores, 4-(4'nitrophenylazo) aniline (DO3) and 4-amino-4'-nitrobiphenyl (ANB), were incorporated into the melamine matrices. The samples exhibit second-order optical nonlinearity after poling and curing at 220 C for 30 min. DO3/HMM and ANB/HMM samples show a second harmonic coefficient, d33 of 10.7 and 1.8 pm/V at 1064 nm, respectively. The temporal stability of both systems has been studied at room temperature as well as at 100 C. Waveguide optical losses of samples at 633 and 830 nm are reported. DTIC

BRIEFING AND REVIEW MEETING IMPLEMENTATION OF THE MILITARY HANDBOOK 17 FOR POLYMER MATRIX AND METAL MATRIX COMPOSITES
Crystal H. Newton 14 Mar. 1994 6 p
(Contract DAAL01-93-C-4064)
(AD-A277446) Avail: CASI HC A02/MF A01

Support of the metal matrix composites effort, as the equivalent of a MIL-HDBK-17 working group, is included in the Secretariat contract. Preparation, of a document for publication was not included in the revised proposal since this was not mentioned in the RFP. The draft outline of the metal matrix handbook was revised. A volume with three parts is planned. Volunteers will draft some of the sections and additional sections will be written by the MMCIAC. The goal is a draft handbook by the New Orleans meeting, sufficient to be assigned a military handbook number. In addition to draft handbook sections, test matrix information is under development. Buchanan at McDonald Douglas has a MMC database he is willing to contribute to the handbook. DTIC

DEVELOPMENT AND PRELIMINARY EVALUATION OF ARYL ESTER BOUNDARY ADDITIVES FOR PERFLUOROPOLYETHERS
John R. Williams (Draper, Charles Stark Lab., Inc., Cambridge, MA.), Debra K. Feuchter (Calspan Corp., Fairview Park, OH.), and William R. Jones, Jr. May 1994 10 p Presented at the International Rolling Element Bearing Symposium, San Diego, CA, 12-14 Apr. 1994; sponsored by DOD
(Contract NAS3-25685; RTOP 233-02-0D)
(NASA-TM-106603; E-8878; NAS 1.15:106603) Avail: CASI HC A02/MF A01

A series of additives were developed for evaluation as boundary lubrication enhancers for perfluoropolyethers. They are composed of a hydrocarbon aryl component (for lubrication improvement) and a fluorinated side chain (for solubility enhancement). The two moieties are joined by an ester linkage. Five boundary additives were evaluated in a perfluoropolyether basestock (Fomblin Z25) using a specially designed four-ball apparatus. Additives were evaluated at a one wt percent concentration. Conditions included: an atmosphere of dry air at atmospheric pressure, a 200N load, a speed of 100 rpm, room temperature, and 440C stainless steel specimens. Two monoesters, 2,4,6-trimethyl E2 and H5PDFO yielded wear rate reductions of approximately 60 and 35 percent, respectively. One diester, H4(E2)(sub 2), had no activity, while two other diesters (a diester of bisphenol A and H4(E4)(sub 2)) were pro-wear. Author

A RELAXATION STUDY OF POLED NONLINEAR OPTICAL POLYMERS BY INFRARED REFLECTION-ABSORPTION SPECTROSCOPY
Sutiyao Marturunkakul, Jeng I. Chen, Y. M. Chen, J. Kumar, and Sukany K. Tripathy 14 Mar. 1994 6 p
(Contract N00014-90-J-1148)
(AD-A277513; Rept-1148-94-05) Avail: CASI HC A02/MF A01

The relaxation of poled nonlinear optical (NLO) chromophores in polymer films was characterized by infrared reflection-absorption spectroscopy. Both a guest-host system and a photo-crosslinkable polymer system were investigated. Polymethylmethacrylate doped with either 2-methyl 4-nitroaniline or 4(4'-nitrophenylazo) aniline was studied. The photo-crosslinkable polymer system, polyvinylcinnamate doped with 3-cinnamoyloxy 4-(4-(N,N-diethylamino) 2-cinnamoyloxy phenyl azo)nitrobenzene, was also investigated. Doped NLO active molecules were aligned using the corona poling technique. Infrared spectra as a function of time were used to monitor the relaxation behavior of the oriented dyes after poling. Relaxation of NLO molecules was followed at various characteristic vibrational frequencies. The relaxation behavior of both systems were found to be consistent with those studied by the second harmonic generation technique. DTIC

THE FERROELECTRIC BEHAVIOR OF ODD-NUMBERED NYLONS
B. Z. Mei, J. I. Scheinbeim, and B. A. Newman Aug. 1993 24 p
(Contract N00014-91-J-1078)
(AD-A278126; TR-29-ONR) Avail: CASI HC A03/MF A01

The combined results of the present investigation of Nylon 5 and Nylon 9 and the previous investigation of Nylon 11 and Nylon 7 reveal that the odd-numbered nylons exhibit classic ferroelectric J-E and D-E hysteresis behavior at room temperature. In addition, the remanent polarization, P, of Nylon 5 and Nylon 9 are found to be 125 approximately 130 mC/sq meters and 65 approximately 70 mC/sq meters, respectively. The remanent polarization of the odd nylon series is observed to increase linearly with increasing dipole density as does the melting point. The coercive field also shows a linear increase with dipole density. The present study also shows that both uniaxially oriented and unoriented odd-numbered nylons exhibit ferroelectric hysteresis behavior, and that the ferroelectric response can be significantly enhanced by uniaxial orientation. NOVEL POLYDIACETYLENES AS MATERIALS FOR SECOND AND THIRD ORDER NONLINEAR OPTICS
W. H. Kim, B. Bihari, C. E. Masse, J. Kumar, and Sukany K. Tripathy 18 Mar. 1994 8 p
(Contract N00014-90-J-1148)
(AD-A277512; Rept-1148-94-09) Avail: CASI HC A02/MF A01

The objective of this investigation was to develop stable nonlinear optical (NLO) materials which possess both second and third order NLO properties. These materials were envisioned as having a polydiacetylene (PDA) backbone with a second order active NLO chromophoric substituent consisting of a donor group, a p-conjugated bridge, and an acceptor group. The choice of a PDA backbone in this investigation was twofold. In terms of third order NLO properties, the extensive p-conjugation of the PDA backbone leads to large ultrafast third order effects. In terms of second order NLO properties, the high thermal stability and rigidity of the PDA matrix in a perfect polymeric single crystal is expected to prevent the randomization of the NLO chromophores in the noncentrosymmetric environment. This paper focuses on the synthesis and NLO properties of the unsymmetrical diacetylene monomers, ((9-Butoxy carbonyl) methyl urethanyl) 1-(4-urethanyl 4'-urethanyl 4'-nitrobiphenyl)-nona 2,4-diyne, and ((9-Butoxy carbonyl)methyl urethanyl) 1-(4-urethanyl 4'-nitroazo-benzene)-nona 2,4-diyne. The high entropy flexible urethanyl side group was chosen to satisfy the monomer packing requirements for polymerization and enhance the solubility of the PDA's. DTIC

(AD-A278003; TR-28) Avail: CASI HC A03/MF A01

Most studies of ferroelectricity and piezoelectricity in polymers have been directed towards poly(vinylidene fluoride) and its copolymers. A long series of investigations in our laboratory of the odd-numbered nylons has culminated in the discovery that these polymers are also ferroelectric and piezoelectric. These studies are important not only to test the generality of the phenomena discovered in poly(vinylidine fluoride), but to examine the effect of hydrogen bonding on ferroelectricity and piezoelectricity in polymers. One important result of this work was the discovery of a mechanism to stabilize the piezoelectric activity of these hydrogen bonded polymers to the melting point. DTIC

EVALUATION OF THE HUGHES CONVERSION COATING TOUCH-UP PEN Final Report, Jan. - Jun. 1993
John Deitzel (Jaylords, Inc., Philadelphia, PA.) and Stephen J. Spadafora 22 Jul. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278398; NAWCADWAR-93050-60) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Chromate conversion coatings are common surface pretreatments for aluminum substrates on Navy aircraft, weapon platforms, and ground support equipment. While this chromated process performs satisfactorily, future restrictions require the elimination or minimization of chromium emissions from this process. One approach to minimize emissions is through the incorporation of new touch-up procedures. A chemical film touch-up pen developed by Hughes Ground Systems Group offers the potential to provide the required paint adhesion and corrosion protection for aluminum for repair applications. The Naval Air Warfare Center Aircraft Division at Warminster performed a study of this pen and the following is a description of the evaluation. DTIC

ELECTROSTRICTIVE RESPONSE OF ELASTOMERIC POLYMERS
Jerry I. Scheinbeim, Brian A. Newman, Z. Y. Ma, and J. W. Lee Aug. 1993 14 p
(Contract N00014-91-J-1078)
(AD-A277983; TR-30) Avail: CASI HC A03/MF A01

It is well known that the electrostrictive response of all materials is small at low applied electric fields. However, the electrostrictive strains (S) are related to the square of the applied field (E). It therefore appeared reasonable to assume that for a soft polymeric material, a large thickness response, d(sub T)(d(sub T) = partial derivative of S/partial derivative of E), might be obtained by application of sufficiently high D.C. bias fields (approx. 20MV /m) to a film while driving the film with an A.C. signal. Under such high electric fields, d(sub T) values greater than 3 A/V were obtained for a low crystallinity poly(vinylidene fluoride) (PVF2) film containing 65% by weight of a plasticizer tricresyl phosphate (TCP). Values of 6 A/V were obtained for certain classes of thermoplastic elastomers, i.e., polyurethanes. These values are considerably greater than those obtained from conventional piezoelectric ceramic materials and an order of magnitude greater than the 0.25 A/V obtained from polarized PVF2. In addition, large elastic strains (greater than 3%) were observed as a function of applied D.C. field. DTIC

(AD-A277514; Rept-1148-94-08) Avail: CASI HC A03

Successful development of materials for photonic applications requires an understanding of the nonlinear optical process, chemistry and processing of materials, and technologies for device fabrications. We are able to successfully use different chemistries to develop several types of crosslinked and networked systems. Significant progress in improving material properties has been accomplished. Promising results have been observed in several materials developed. A prototype frequency doubling device has been prepared; second harmonic Cerenkov radiation emitting green and blue light have been observed. Relevant chemical modifications to fine-tune or enhance the desired properties will need to be iteratively performed to obtain optimized properties for practical applications. DTIC

NOVEL SOL-GEL DEPOSITION FOR REPAIR OF CONDUCTING PATHS IN POLYCERAMIC SYSTEMS Final Report, 1 Jul. - 31 Dec. 1993
Guang-Way Jang 24 Feb. 1994 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-C-0048)
(AD-A278381; AFOSR-94-0187TR) Avail: CASI HC A03

The present project involves research and development of conducting polymer sol-gel composites for repair of conducting paths in polyceramic systems. During Phase 1, we developed and carried out the synthesis of processible conducting polymers and organic/inorganic hybrid sol-gel materials. Sol-gel composite materials prepared during Phase 1, I have high electrical conductivity (ca. 30 S/cm) and adhere strongly on the surface of ceramic materials. The conductivity of ITO glass was the same as its original value after repairing a crack with these sol-gel composites. Conductive sol-gel composites can be prepared with a very small amount of processible conducting polymers, ca. 3%. Composites with high concentration of conducting polymers (70% - 90%), however, showed better stability. Sol-gel metal oxides and conducting polymers are also ideal electrode materials for the fabrication of multilayer capacitors and rechargeable batteries. Upon completion of the present work, it is evident that the feasibility of the technology proposed for repairing conducting paths in polyceramic systems was demonstrated. DTIC

NOVEL PRECURSOR APPROACHED FOR CMC DERIVED BY POLYMER PYROLYSIS Final Report, 15 Dec. 1990 - 14 Dec. 1993
Wayde R. Schmidt 15 Feb. 1994 56 p
(Contract F49620-91-C-0017)
(AD-A278383; R94-970051-3; AFOSR-94-0198TR) Avail: CASI HC A04/MF A01

A family of reactive endblocked poly(methylvinylsilane), PMVS, polymers was developed for fabricating fiber-reinforced silicon carbide ceramic matrix composites (CMC's). Control of reaction conditions was optimized to synthesize a baseline PMVS in multiple batches and sufficient quantity to examine modifications of the polymer chemistry during processing and pyrolysis. The conversion of PMVS to carbon-rich nanocrystalline silicon carbide ceramic was studied using a variety of analytical techniques, including thermal analysis, infrared and nuclear magnetic resonance spectroscopy, x-ray diffraction, and electron microscopy. The excess C in PMVS ceramic chars was effectively scavenged with an added Si source. Perhydropoly(silazane), PHPS, provided a polymer precursor source of Si3N4 and excess Si. Blends of PHPS and PMVS had higher char yields (70-85%) than either component polymer and generated novel nanocrystalline ceramics with heating to 1600 C. Crystal growth was inhibited in chars derived from these blends. Added elemental Si reacted with the excess C and enhanced crystal growth of SiC above the melting point of Si. Representative CMC's with good mechanical properties were fabricated using several PMVS-based matrix sources. The CMC's showed load vs. deflection curves typical of non-brittle failure and tensile specimens showed fibrous failure. DTIC

This paper reviews the status of the laser diode ignition (LDI) program at Sandia National Labs. One-watt laser diodes have been characterized for use with a single explosive actuator. Extensive measurements of the effect of electrostatic discharge (ESD) pulses on the laser diode optical output have been made. Characterization of optical fiber and connectors over temperature has been done. Multiple laser diodes have been packaged to ignite multiple explosive devices and an eight element laser diode array has been recently tested by igniting eight explosive devices at predetermined 100 ms intervals. R. W. Bickes, Jr., M. C. Grubelich, J. K. Hartman, C. B. McCampbell, and J. K. Churchill 1993 4 p Presented at the 1994 National Aeronautics and Space Administration Pyrotechnic Systems Workshop, Albuquerque, NM, 8-9 Feb. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006467; SAND-93-1734C; CONF-940245-1) Avail: CASI HC A01/MF A01

A conventional NSI (NASA standard initiator) normally employs a hot-wire ignition element to ignite ZPP (zirconium potassium perchlorate). With minor modifications to the interior of a header similar to an NSI device to accommodate an SCB (semiconductor bridge), a low cost initiator was obtained. In addition, the ZPP was replaced with THKP (titanium subhydride potassium perchlorate) to obtain increased overall gas production and reduced static-charge sensitivity. This paper reports on the all-fire and no-fire levels obtained and on a dual mix device that uses THKP as the igniter mix and a thermite as the output mix. DOE

SCENARIOS FOR MULTI-UNIT INERTIAL FUSION ENERGY PLANTS PRODUCING HYDROGEN FUEL
B. G. Logan Dec. 1993 6 p Presented at the 11th International Workshop on Laser Interaction and Related Plasma Phenomena, Monterey, CA, 25-29 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-006614; UCRL-JC-114495; CONF-931048-6) Avail: CASI HC A02

This work describes the following: (1) the motivation for considering fusion, in general, and Inertial Fusion Energy (IFE), in particular, to produce hydrogen fuel powering low-emission vehicles; (2) the general requirements for any fusion electric plant to produce hydrogen by water electrolysis at costs competitive with present consumer gasoline fuel costs per passenger mile, for advanced car architectures meeting President Clinton's 80 mpg advanced car goal; and (3) a comparative economic analysis for the potential cost of electricity (CoE) and corresponding cost of hydrogen (CoH) from a variety of multi-unit IFE plants with one to eight target chambers sharing a common driver and target fab facility. Cases with either heavy-ion or diode-pumped, solid-state laser drivers are considered, with 'conventional' indirect drive target gains versus 'advanced, e.g. Fast Ignitor' direct drive gain assumptions, and with conventional steam balance-of-plant (BoP) versus advanced MHD plus steam combined cycle BoP, to contrast the potential economics under 'conventional' and 'advanced' IFE assumptions, respectively. NOVEL APPROACHES TO THE PRODUCTION OF HIGHER ALCOHOLS FROM SYNTHESIS GAS
22 Nov. 1993 25 p
(Contract DE-AC22-90PC-90043)
(DE94-006770; DOE/PC-90043/T12) Avail: CASI HC A03/MF A01

This document reports work during this quarter on the project to produce higher alcohols from synthesis gas. A set of four methanol synthesis runs was conducted. Significant catalyst deactivation was experienced, and essentially all of the oil was lost from the reactor over the course of two weeks of operation. Three screening runs of potential high temperature oil were also conducted. However, essentially no oil remained in the reactor after completion of each run. A 1%Rh/1.3%Re/Al2O3 catalyst was prepared from Re and Rh carbonyls with the objective of obtaining intimate contact between Rh and Re atoms. The catalytic activity of this catalyst was explored. Mo was deposited on the catalyst from both molybdenum hexacarbonyl (Mo(CO)6) and (NH4)6Mo7O24(center dot)4H2O.The catalytic activity of the molybdenum promoted catalysts was found to be the highest achieved to date under this contract. HIGH OCTANE ETHERS FROM SYNTHESIS GAS-DERIVED ALCOHOLS
K. Klier, R. G. Herman, O. C. Feeley, and M. A. Johansson Nov. 1993 20 p
(Contract DE-AC22-90PC-90044)
(DE94-006774; DOE/PC-90044/12) Avail: CASI HC A03/MF A01

The objective of the proposed research is to synthesize oxygenated fuel ethers, primarily methyl isobutyl ether (MIBE) and methyl tertiary butyl ether (MTBE), directly from coal-derived H2/CO/CO2 synthesis via alcohol mixtures that are rich in methanol and 2-methyl-1-proanol (isobutanol). The overall scheme involves gasification of coal, purification and shifting of the synthesis gas, higher alcohol synthesis, and direct synthesis of ethers. Both organic and inorganic catalysts will be investigated, and the better catalysts will be subjected to long term performance studies. The project is divided into the following three tasks: (1) synthesis of high octane ethers from alcohol mixtures containing predominantly methanol and 2-methyl-1-propanol over superacid resins, (2) inorganic catalysts for the synthesis of high octane ethers form alcohols, and (3) long term performance and reaction engineering for scale-up of the alcohols-to-ether process. A summary of technical progress is provided in this report. DOE

THE HYDROGEN HYBRID OPTION
J. R. Smith 15 Oct. 1993 12 p Presented at the Workshop on Advanced Components for Electric and Hybrid Electric Vehicles, Gaithersburg, MD, 27-28 Oct. 1993
(Contract W-7405-eng-48)
(DE94-006733; UCRL-JC-115425; CONF-9310282-1) Avail: CASI HC A03/MF A01

The energy efficiency of various piston engine options for series hybrid automobiles are compared with conventional, battery powered electric, and proton exchange membrane (PEM) fuel cell hybrid automobiles. Gasoline, compressed natural gas (CNG), and hydrogen are considered for these hybrids. The engine and fuel comparisons are done on a basis of equal vehicle weight, drag, and rolling resistance. The relative emissions of these various fueled vehicle options are also presented. It is concluded that a highly optimized, hydrogen fueled, piston engine, series electric hybrid automobile will have efficiency comparable to a similar fuel cell hybrid automobile and will have fewer total emissions than the battery powered vehicle, even without a catalyst. ADVANCED THERMALLY STABLE JET FUELS
H. H. Schobert, S. Eser, C. Song, P. G. Hatcher, P. M. Walsh, and M. M. Coleman Jul. 1993 124 p
(Contract DE-FG22-92PC-92104)
(DE94-006760; DOE/PC-92104/T3) Avail: CASI HC A06/MF A02

This project was initiated on August 1, 1992. The starting date resulted in this project being one month out of synchronization with the normal quarterly calendar (i.e., January, April, July, and October). On advice of Mr. John Augustine, DOE/PETC, the present report is prepared to cover only two months work, so that future quarterly reports will be aligned with the conventional reporting schedule. A significant pressure dependence was observed for the pyrolysis of n-tetradecane at 450 C for 30 min. It appears that at least two processes are affected by the reactant pressure, but in opposite directions. The influence of inert gas pressure is dependent on both the initial sample volume and the pressure range. However, when the inert gas pressure is within a certain specific range, the changes in the sample volume have no impact on n-tetradecane conversion. Below or above this range, increasing inert gas pressure can either decrease or increase conversion, depending on the sample volume. DOE

HETEROGENEOUS CATALYTIC PROCESS FOR ALCOHOL FUELS FROM SYNGAS
Jul. 1993 23 p
(Contract DE-AC22-91PC-90046)
(DE94-008729; DOE/PC-90046/T8) Avail: CASI HC A03/MF A01

The principal objectives of this project are to discover and evaluate novel heterogeneous catalysis for conversion of syngas to oxygenates having use as fuel enhancers, to explore novel reactor and process concepts applicable in this process, and to develop the best total process for converting syngas to liquid fuels. This project is being pursued as two concurrent tasks. Task 1 involves catalyst research and development and is being largely conducted by catalyst chemists and analytical specialists. Task 2 is largely an engineering activity, and includes process conceptualization and economics and bench-scale process evaluation of systems developed in Task 1. The current targets for isobutanol-producing catalysts are to produce an equimolar mixture of methanol and isobutanol with a productivity for isobutanol of more than 50 g/Kg-hr. The present report describes technical progress in Task 1, Catalyst Studies, in catalyst preparation (potassium effects) and in determining the effects of process variables on catalyst performance. Task 1 conclusions are presented. Progress in Task 2, Engineering Studies, is reported in reaction engineering. Conclusions reached from the engineering studies are also presented. DOE

AN EXPERIMENTAL STUDY OF VOID FORMATION DURING ALUMINUM SOLIDIFICATION IN REDUCED GRAVITY Ph.D. Thesis
Francis Paul Chiaramonte, III 1993 133 p
Avail: Univ. Microfilms Order No. DA9326130

Void formation due to volumetric shrinkage and liquid/vapor reorientation during aluminum solidification was observed in real time using a radiographic viewing system in normal and reduced gravity. An end-chill directional solidification furnace with water quench was designed and constructed to solidify aluminum samples during the approximately 16 seconds of reduced gravity (+/- 0.02 g) achieved by flying an aircraft through a parabolic trajectory. In the first series of tests, the aluminum was contained in a vacuum sealed, pyrolytic boron nitride crucible. An ullage space was present during each test. Void formation was recorded for two cases: a nonwetting system and a wetting system where wetting occurs between the aluminum and the crucible lid. The void formation in the nonwetting case was similar in normal and reduced gravity, with a single vapor cavity forming at the top of the crucible. In the wetting case in reduced gravity, surface tension caused two voids to form in the top corners of the crucible, but in normal gravity only one large void forms across the top. In the second series of tests, the aluminum was contained in a pyrolytic boron nitride crucible which was placed in a stainless steel container and sealed in an Ar/4 percent H2 environment. An ullage space was present during each test.

Void formation was recorded for two cases: a nonwetting system and a wetting system where wetting occurs between the aluminum and one side wall and lid. The void formation in the nonwetting case was similar in normal and reduced gravity with a single vapor cavity forming at the top of the crucible; although the meniscus became more convex in reduced gravity. In the wetting case, the aluminum did not climb up the corners in one-g and one large symmetric void resulted at the top when solidified. In the wetting case during reduced gravity, the molten aluminum was drawn up the wetted wall and partially across the lid by a capillary underpressure; however, on the nonwetting wall the aluminum moved down. One void resulted along the nonwetting side of the container continuing to the top on the same side. Dissert. Abstr.

BOUNDARY ELEMENT ANALYSIS OF THREE-DIMENSIONAL NONLINEAR HYDRODYNAMICS IN A REDUCED GRAVITY ENVIRONMENT Ph.D. Thesis
Stephen Holbrook Sutherland 1992 172 p
Avail: Univ. Microfilms Order No. DA9318140

The development and implementation of a numerical technique for solving problems in two and three dimensional nonlinear hydrodynamics is described. The computational method, which employs both boundary element and finite element techniques, is an extension to three dimensions of recently developed two dimensional approaches supplemented with an explicit treatment of surface tension effects. Four, eight, and twelve node quadrilateral elements are implemented in the method. All element integrals that arise in the discretization process are evaluated numerically, which enables modeling of very general fluid domains. Test cases involving two and three dimensional nonlinear hydrodynamics including nonlinear solitary wave propagation and run-up, two dimensional nonlinear standing waves with and without surface tension effects, harmonic wave excitation in a cylindrical geometry, and axisymmetric free oscillation of an annular fluid body under low-gravity conditions are solved with the method to demonstrate its capability and accuracy. The test-case analysis predictions are compared with theoretical results and experimental data with good correlation obtained in each instance. Dissert. Abstr.

A LARGE MOTION ZERO-GRAVITY SUSPENSION SYSTEM FOR EXPERIMENTAL SIMULATION OF ORBITAL CONSTRUCTION AND DEPLOYMENT M.S. Thesis
Timothy Milton Straube Dec. 1993 62 p
(Grants NAGw-1388; NAG1-1490)
(NASA-CR-195881; NAS 1.26:195881; CSC-93-34) Avail: CASI HC A04/MF A01

The design and implementation of a vertical degree of freedom suspension system is described which provides a constant force off-load condition to counter gravity over large displacements. By accommodating motions up to one meter for structures weighing up to 100 pounds, the system is useful for experiments which simulate orbital construction events such as docking, multiple component assembly, or structural deployment. A unique aspect of this device is the combination of a large stroke passive off-load device augmented by electromotive torque actuated force feedback. The active force feedback has the effect of reducing break-away friction by a factor of twenty over the passive system alone. The thesis describes the development of the suspension hardware and the control algorithm. Experiments were performed to verify the suspensions system's effectiveness in providing a gravity off-load and simulating the motion of a structure in orbit. Additionally, a three dimensional system concept is presented as an extension of the one dimensional suspension system which was implemented. Author (revised)

Experience has shown that release to the atmosphere of large quantities of chemicals which are foreign to nature often leads to unforeseen problems. A better strategy must be to use substances which are already present in the biosphere, and for which natural circulation systems already exist. Ammonia has been used for generations and can be applied successfully for a wide field. Propane has advantages for some special applications. Recent research has shown that carbon dioxide can be used as a near ideal refrigerant in many cases with new and energy efficient thermodynamic cycles. NTIS

EXPANDABLE PATTERN CASTING RESEARCH
1993 104 p Prepared in cooperation with Southern Research Inst., Birmingham, AL
(Contract DE-FC07-89ID-12869)
(DE94-004342; DOE/ID-12869/3) Avail: CASI HC A06/MF A02

The Expandable Pattern Casting (EPC) Process is a developing foundry technology that allows designers the opportunity to consolidate parts, reduce machining, and minimize assembly operations. An air gauging system was developed for measuring foam patterns; exact shrinkage depended on type and density of the foam. Compaction studies showed that maximum sand densities in cavities and under overhangs are achieved with vibrational amplitudes 0.001-0.004 in., and that sand moved most freely within a few inches of the top free surface. Key to complete mold filling while minimizing casting defects lies in removing the foam decomposition products. The most precise iron castings were made by EPC in four commercial EPC foundries, with attention paid to molding and compaction. EP cast 60-45-12 ductile iron had yield strengths, ultimate strengths, and elastic modulus similar to conventionally cast ductile iron cast from the same ladle. DOE

THE 4 K STIRLING CRYOCOOLER DEMONSTRATION Final Report No. 8, 1 May 1990 - 30 Apr. 1992

W. Dodd Stacy 22 Sep. 1992 38 p

(Contract NAS7-1111; SBIR-08.12-3800)

(NASA-CR-191792; NAS 1.26:191792; TM-1563) Avail: CASI HC A03/MF A01

This report briefly summarizes the results and conclusions from an SBIR program intended to demonstrate an innovative Stirling cycle cryocooler concept for efficiently lifting heat from 4 K. Refrigeration at 4 K, a temperature useful for superconductors and sensitive instruments, is beyond the reach of conventional regenerative thermodynamic cycles due to the rapid loss of regenerator matrix heat capacity at temperatures below about 20 K. To overcome this fundamental limit, the cryocooler developed under this program integrated three unique features: recuperative regeneration between the displacement gas flow streams of two independent Stirling cycles operating at a 180 degree phase angle, tailored distortion of the two expander volume waveforms from sinusoidal to perfectly match the instantaneous regenerator heat flux from the two cycles and thereby unload the regenerator, and metal diaphragm working volumes to promote near isothermal expansion and compression processes. Use of diaphragms also provides unlimited operating life potential and eliminates bearings and high precision running seals. A phase 1 proof-of-principle experiment demonstrated that counterflow regenerator operation between 77 K and 4 K increases regenerator effectiveness by minimizing metal temperature transient cycling. In phase 2, a detailed design package for a breadboard cryocooler was completed. Fabrication techniques were successfully developed for manufacturing high precision miniature parallel plate recuperators, and samples were produced and inspected. Process development for fabricating suitably flat diaphragms proved more difficult and expensive than anticipated, and construction of the cryocooler was suspended at a completion level of approximately 75%. Subsequent development efforts on other projects have successfully overcome diaphragm fabrication difficulties, and alternate funding is currently being sought for completion and demonstration testing of the 4 K Stirling cryocooler.

LLNL CASTING TECHNOLOGY

A. B. Shapiro, ed. and W. J. Comfort, III, ed. Jan. 1994 9 p

(Contract W-7405-eng-48)

(DE94-008282; UCRL-ID-116320) Avail: CASI HC A02/MF A01

Competition to produce cast parts of higher quality, lower rejection rate, and lower cost is a fundamental factor in the global economy. To gain an edge on foreign competitors, the US casting industry must cut manufacturing costs and reduce the time from design to market. Casting research and development (R&D) are the key to increasing US competiveness in the casting arena. Lawrence Livermore National Laboratory (LLNL) is the home of a wide range of R&D projects that push the boundaries of state-of-the art casting. LLNL casting expertise and technology include: casting modeling research and development, including numerical simulation of fluid flow, heat transfer, reaction/solidification kinetics, and part distortion with residual stresses; special facilities to cast toxic material; extensive experience casting metals and nonmetals; advanced measurement and instrumentation systems. Department of Energy (DOE) funding provides the leverage for LLNL to collaborate with industrial partners to share this advanced casting expertise and technology. At the same time, collaboration with industrial partners provides LLNL technologists with broader insights into casting industry issues, casting process data, and the collective experience of industry experts. Casting R&D is also an excellent example of dual-use technology; it is the cornerstone for increasing US industrial competitiveness and minimizing waste nuclear material in weapon component production. Annual funding for casting projects at LLNL is $10M, which represents 1% of the total LLNL budget. Metal casting accounts for about 80% of the funding. Funding is nearly equally divided between development directed toward US industrial competitiveness and weapon component casting. DOE

METAL HYDRIDE HEAT PUMP ENGINEERING DEMONSTRATION AND EVALUATION MODEL Final Report

Franklin E. Lynch Oct. 1993 64 p

(Contract NAS9-17819)

(NASA-CR-188286; NAS 1.26:188286) Avail: CASI HC A04/MF A01

Future generations of portable life support systems (PLSS's) for space suites (extravehicular mobility units or EMU's) may require regenerable nonventing thermal sinks (RNTS's). For purposes of mobility, a PLSS must be as light and compact as possible. Previous venting PLSS's have employed water sublimators to reject metabolic and equipment heat from EMU's. It is desirable for long-duration future space missions to minimize the use of water and other consumables that need to be periodically resupplied. The emission of water vapor also interferes with some types of instrumentation that might be used in future space exploration. The test article is a type of RNTS based on a metal hydride heat pump (MHHP). The task of reservicing EMU's after use must be made less demanding in terms of time, procedures, and equipment. The capability for quick turnaround post-EVA servicing (30 minutes) is a challenging requirement for many of the RNTS options. The MHHP is a very simple option that can be regenerated in the airlock within the 30 minute limit by the application of a heating source and a cooling sink. In addition, advanced PLSS's must provide a greater degree of automatic control, relieving astronauts of the need to manually adjust temperatures in their liquid cooled ventilation garments (LCVG's). The MHHP includes automatic coolant controls with the ability to follow thermal load swings from minimum to maximum in seconds. The MHHP includes a coolant loop subsystem with pump and controls, regeneration equipment for post-EVA servicing, and a PC-based data acquisition and control system (DACS). Derived from text

CONTROLLING HAZARDOUS ENERGY SOURCES (LOCKOUT/TAGOUT)

Manuel B. Dominguez Oct. 1991 16 p

(NASA-TM-105290; E-6627; NAS 1.15:105290) Avail: CASI HC A03/MF A01

The minimum requirements as established by the Occupational Safety and Health Administration (OSHA) standard 29 CFR 1910.147 are discussed for preventing the unexpected operation of equipment or release of energy which could cause injury to personnel, damage to equipment, harm to the environment, or loss or compromise of test data. Safety requirements both for government and contractor personnel are explained for potentially hazardous energy sources during work operations at LeRC (Cleveland and Plum Brook Stations). Basic rules are presented to ensure protection against harmful exposures, and baseline implementation requirements are discussed from which detailed lockout/tagout procedures can be developed for individual equipment items. Examples of energy sources covered by this document include electrical, pneumatic, mechanical, chemical, cryogenic, thermal, spring tension/compression suspended or moving loads, and other potentially hazardous sources. Activities covered by this standard include, but are not limited to, construction, maintenance, installation, calibration, inspection, cleaning, or repair. Author (revised)

CHANNEL EQUALIZATION FOR BLOCK TRANSMISSION SYSTEMS
Ghassan KawasKaleh Jan. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0751-1345)
(TELECOM-93-D-002; ETN-94-95885) Avail: CASI HC A03

For communication over channels subject to fast time variation, for example, the HF channel, the information symbols are arranged in the form of blocks separated by known symbols. Such a system is called a block transmission system. Its known convenient receiver is the Nonlinear Data Directed Estimator (NDDE). Appropriate equalization methods for this system are derived, using a nonstationary innovations representation based on Cholesky factorization in order to define a noise whitener and a maximum likelihood block detector. Zero forcing and minimum mean squared error block linear and block decision feedback equalizers are also derived. Their performances are evaluated and compared. They are shown to perform better than the conventional equalizers. As compared with the NDDE, the deduced block decision feedback equalizers have better performance and are much less complex. Whereas the NDDE uses the Levinson algorithm to solve M/2 Toeplitz systems of decreasing order (where M is the number of symbols per block), the deduced equalizers need to process only one Toeplitz system. The Schur algorithm, proposed for Cholesky factorization, allows the complexity to be further reduced. ESA

PHASE UNWRAPPING PROBLEMS IN ISAR IMAGES [PROBLEMES DE DEVELOPPEMENT DE PHASE DANS LES IMAGES ISAR]
Jean-Pierre Veran Dec. 1992 17 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0751-1345)
(TELECOM-93-D-008; ETN-94-95889) Avail: CASI HC A03

The problem of the phase unwrapping in the ISAR (Interoferometric Synthetic Aperture Radar) images is studied. This problem is tricky when the image is noisy and when the local gradient is high (like in mountainous areas). A theoretical approach is chosen and work in a continuous space is carried out. A formal analogy with a problem of magnetostatics is proposed, and, using simple physics tools, an expression of the unwrapped phase is obtained. Unfortunately this result is not fully transposable to a discrete space (real case). However, implementations which would improve the performance of the existing algorithms are discussed. ESA

(ISSN 0751-1353)
(TELECOM-93-E-018; ETN-94-95904) Avail: CASI HC A10

Autodidactic equalization by adaptive filtering is addressed in a mobile radio communication context. A general method, using an adaptive stochastic gradient Bussgang type algorithm, to deduce two low cost computation algorithms is given: one equivalent to the initial algorithm and the other having improved convergence properties thanks to a block criteria minimization. Two start algorithms are reworked: the Godard algorithm and the decision controlled algorithm. Using a normalization procedure, and block normalization, the performances are improved, and their common points are evaluated. These common points are used to propose an algorithm retaining the advantages of the two initial algorithms. This thus inherits the robustness of the Godard algorithm and the precision and phase correction of the decision control algorithm. The work is completed by a study of the stable states of Bussgang type algorithms and of the stability of the Godard algorithms, initial and normalized. The simulation of these algorithms, carried out in a mobile radio communications context, and under severe conditions on the propagation channel, gave a 75% reduction in the number of samples required for the processing in relation with the initial algorithms. The improvement of the residual error was of a much lower return. These performances are close to making possible the use of autodidactic equalization in the mobile radio system. ESA

Ways of adapting the European Space Agency's role to the new industrial environment of satellite communications, which is characterized by the disappearance of traditional monopolies and the introduction of competition, are presented. As far as ESA is concerned, it is found that a

general consensus exists to recommend that the agency should take a much wider view of its role as a research and development (R&D) organization. It should no longer restrict its field of activity to space technology only, but should take a more global approach. More emphasis should be placed on the development of complete communications systems and of commercial applications. European industry indeed feels very strongly that it is not getting from ESA the support it needs to match the performance of its foreign competitors on the world markets. It can only succeed commercially in the fierce competition with the U.S. and Japan if a substantial R&D program is defined and funded at European level, as required by the magnitude of the financial effort necessary. It is concluded that anything the agency untertakes in the future to redress the situation would produce much greater dividends if it were part of a coherent plan where all the European partners play their role in a cooperative spirit. It is recommended that the European Commission should, as a matter of urgency, take steps to institute a concertation mechanism involving all major players with a view to defining and developing a coherent strategy for Europe. FILTERING AND RECOGNITION OF MOVING BOATS IN RADAR IMAGES [FILTRAGGIO E RICONOSCIMENTO DI NATANTI IN MOVIMENTO IN IMMAGINI RADAR]

Cesare Alippi Jun. 1993 26 p In ITALIAN

(Rept-93-039; ETN-94-95808) Avail: Issuing Activity (Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milan, Italy)

The problems of filtering, recognition, and classification of objects in two dimensional images are addressed. In particular, a problem relating to the recognition of boats in harbors or canals in radar generated images is considered. The main objective is to determine the outlines of ships for subsequent identification of the direction of motion. The solution proposed must respect stringent requirements of real time development. The classical neural solution is considered. The solution is ultimately interpretable as a classical adaptive solution in which the convolution masking coefficients are determined as a function of learning. ESA

AN ADAPTIVE KALMAN FILTER EXCISOR FOR SUPPRESSING NARROWBAND INTERFERENCE

Brian W. Kozminchuk Nov. 1993 47 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A276286; DREO-TN-93-20) Avail: CASI HC A03

Several reports have been written by the author which characterize the performance of a Kalman filtering technique to suppress narrowband interference from direct sequence spread spectrum communications systems in a non-adaptive context, i.e., when the user has some a priori knowledge of the interference characteristics. This report expands on this technique by presenting an adaptive scheme which is useful for the situation when the interference characteristics are unknown. In this context, the Kalman filter must 'learn' to achieve optimal performance through the adjustment of one of its parameters. The criterion for optimality is the minimization of the mean-squared error at the output of the canceller, where this error consists of spread spectrum signal, noise and residual interference. The reasonable assumption is made that minimizing the mean of this squared error with respect to the appropriate Kalman filter parameter is equivalent to minimizing the mean squared value of the residual interference. Examples of the dynamic behavior of the adaptive interference suppressor are presented for narrowband Gaussian noise interference with bandwidths ranging from 1% to 5% of the chip rate. DTIC

SUBSPACE ESTIMATION WITHOUT EIGENVECTORS FOR ADAPTIVE BEAMFORMING

Mylene Toulgoat, Christoph Gierull, and Ross M. Turner Dec. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A276287; DREO-1194) Avail: CASI HC A03

This report describes a new fast projection technique for adaptive beamforming. It is based on a technique proposed by Yeh where Gram-Schmidt orthogonalization is applied to N rows of the covariance matrix to obtain the signal subspace. In Yeh's technique, N is equal to L the number of jammers. This technique, applied to bearing estimation, requires a priori knowledge of the number of sources. Even though it gives good results when the number of sources is much smaller than the number of array elements, the performance of Yeh's technique degrades severely as the number of jammers increases. We improve the technique by taking a larger number of rows in the orthogonalization: we add a thresholding procedure to the technique in order to optimize N. We compared this new technique, called Subspace Estimation Without Eigenvectors (SEWE), with other fast projection techniques. SEWE was shown to give superior performance in terms of the Signal-to-Noise-Plus-Jammer Ratio achievable with a given computational load, except when a very high SNJR is required. DTIC

SPREAD-SPECTRUM RADIO SYSTEMS AND NETWORKS Final Report, 21 May 1991 - 20 Jul. 1993

Michael B. Pursley and Dilip V. Sarwate 25 Oct. 1993 6 p

(Contract DAAL03-91-G-0154)

(AD-A276449; ARO-27994.10-EL) Avail: CASI HC A02/MF A01

As part of the research completed under the subject contract, we showed that the effectiveness of error-control coding in a frequency-hop radio system can be increased greatly by the use of side information developed in the radio receiver. For slow-frequency-hop transmission, the inclusion of test symbols in each dwell interval provides a simple method for the derivation of side information for that dwell interval. Requirements on the reliability of the side information are presented in two other publications, and their implications in determining the necessary number of test symbols per dwell interval are described. When applied to a frequency-hop radio, concatenated coding provides a method for simultaneously achieving a larger communication range and greater protection against partial-band interference than can be obtained by systems without error-control coding or even most systems with a single form of coding. FEATURE DISCOVERY IN GRAY LEVEL IMAGERY FOR ONE-CLASS OBJECT RECOGNITION

M. W. Koch and M. M. Moya 1993 7 p Presented at the IEEE World Congress on Computational Intelligence, Orlando, FL, 26 Jun. - 2 Jul. 1993

(Contract DE-AC04-94AL-85000)

(DE94-005268; SAND-93-4040C; CONF-9306304-1) Avail: CASI HC A02/MF A01

Feature extraction transforms an object's image representation to an alternate reduced representation. In one-class object recognition, we would like this alternate representation to give improved discrimination between the object and all possible non-objects and improved generation between different object poses. Feature selection can be time-consuming and difficult to optimize so we have investigated unsupervised neural networks for feature discovery. We first discuss an inherent limitation in competitive type neural networks for discovering features in gray level images. We then show how Sanger's Generalized Hebbian Algorithm (GHA) removes this limitation and describe a novel GHA application for learning object features that discriminate the object from clutter. Using a specific example, we show how these features are better at distinguishing the target object from other nontarget object with Carpenter's ART 2-A as the pattern classifier. DOE

KALMAN FILTERING APPROACH TO BLIND EQUALIZATION M.S. Thesis

Mehmet Kutlu Dec. 1993 79 p

(AD-A276320) Avail: CASI HC A05/MF A01

Digital communication systems suffer from the channel distortion problem which introduces errors due to intersymbol interference. The solution to this problem is provided by equalizers which use a training sequence to adapt to the channel. However in many cases in which a training sequence is unfeasible, the channel must be adapted blindly. Most of the blind equalization algorithms known so far have problems of convergence to local minima. Our intention is to offer an alternative approach by using extended Kalman filtering and hidden Markov models. They seem to yield more efficient algorithms which take the statistics of the transmitted sequence into consideration. The theoretical development of these new algorithms is

discussed in this thesis. Also these algorithms have been simulated under different conditions. The results of simulations and comparisons with existing systems are provided. The models for simulations are presented as MATLAB codes. DTIC

PREDICTING ANTENNA PARAMETERS FROM ANTENNA PHYSICAL DIMENSIONS M.S. Thesis
Steven E. Lundholm Dec. 1993 209 p
(AD-A276442) Avail: CASI HC A10/MF A03

This report details the development and provides the documentation for custom computer software applications that evaluate antenna parameters. The applications are written in Mathcad 3.1 for the following antenna types: linear, planar, and circular arrays; folded dipole; caged dipole; and parabolic reflectors with helical and spiral feeds. Inputs to the applications are limited to the antenna's physical dimensions. In some cases, ground parameters are required. The chapters are structured to provide the user with the necessary information needed to use and interpret the software for each antenna type. The software applications are provided as appendices and give examples of each antenna type. Outputs of the applications provide various numerical and performance predictions, as well as far-field radiation patterns. The results computed are consistent with predictions provided in applicable publications, as well as those calculated by numerical antenna analysis programs such as ELNEC. DTIC

OBSERVATION OF THE TRAVELING COMPONENT OF AN X RAY STANDING WAVE FIELD
B. Lai, W. B. Yun, J. Chrzas, and P. J. Viccaro 1994 16 p
(Contract W-31-109-eng-38)
(DE94-007671; ANL/APS/PP-73889) Avail: CASI HC A03/MF A01

We present the first systematic experimental study of the traveling component of a standing wave field, formed by interference of an incident beam with its specularly reflected part from a plane interface. The traveling component of the standing wave field propagates parallel to the interface and its existence manifests the dynamical aspect of the standing wave field. In our experiment, a multilayer structure was used to aid in the observation of the traveling wave component. The data measured are explained using a finite thickness diffraction grating model. DOE

THE HIGH-FREQUENCY BENCHMARK PROPAGATION PROGRAM Final Report
J. A. Ferguson and C. H. Shellman Oct. 1993 18 p
(AD-A276323; NCCOSC/RDT/E-TD-2608) Avail: CASI HC A03/MF A01

The High-Frequency Benchmark is a computer code being developed to employ a sophisticated ray tracing program coupled with a state-of-the-art ionospheric model chosen by the user. The merging of these two major components depends critically on the development of a spatial smoothing routine that accepts arbitrary ionospheric models as inputs. A significant improvement in the spatial interpolation has been made which enhances the flexibility of the model. The latest version of the Parameterized Ionospheric Model has been incorporated. This report describes these improvements and enhancements. DTIC

FORMULATION OF TIME-DOMAIN PLANAR NEAR-FIELD MEASUREMENTS WITHOUT PROBE CORRECTION Report, Sep. 1991 - Aug. 1993
Thorkild B. Hansen and Arthur D. Yaghjian Sep. 1993 106 p
(AF Proj. 2304)
(AD-A276380; RL-TR-93-210) Avail: CASI HC A06/MF A02

This report addresses the problem of formulating planar near-field antenna measurements in the time domain, so that a single set of time-domain near-field measurements yields the far-field pattern in the time domain or over a wide range of frequencies. The time-domain planar near-field techniques are developed for both acoustic and electromagnetic fields and the space outside the region occupied by the antenna is assumed to be isotropic and homogeneous. Probe correction is ignored, that is, it is assumed that the probe is ideal so that the exact values of the field on the measurement plane are known. Two fundamentally different approaches are used in deriving time-domain formulas which give the fields in the half space z greater than z sub 0, in terms of their values on the plane z = z sub 0. In the first approach the time-domain formulas are obtained by inverse Fourier transforming the corresponding frequency-domain formulas. Since this approach requires extensive use of the frequency domain near-field formulas, we start by giving a rigorous derivation and review of the frequency-domain formulation that addresses a number of subtleties that have not been dealt with adequately in the literature. As part of this review, planar near-field formulas for the static electric and magnetic fields are derived for the first time. In the second approach the time-domain near-field formulas are derived directly in the time domain. The equivalence of the resulting time-domain formulas obtained by the two different approaches demonstrates the validity of the formulas and the utility of both approaches. DTIC

(Contract N00014-91-J-4063)
(AD-A275967) Avail: CASI HC A02/MF A01

Communications techniques and performance models are devised for communications networks in which mobile platforms, volatile traffic patterns, and interference are significant features. The main focus is on network organization and control configurations that support communications among semi-autonomous mobile platforms. Example platforms can support data gathering sensors and communications equipment aboard guided or maneuverable space vehicles satellites, aircraft, ships, or grounded vehicles or persons. Network configurations with limited and/or shared communications resources are considered. Analytical models are devised to characterize major performance issues. Matters of concern include maintaining network connectivity with mobile platforms that have active communications links, methods for allocating communications resources to gateways, dynamic assignment of resources, and access rights. Topics investigated have included: acquisition of spread spectrum signals, low-delay channel access protocols, call hand-off schemes, telecommunications traffic performance of mobile networks, computation vs. communication considerations, high speed packet switching, and aspects of self-organizing communications networks. A STUDY OF THEORETICAL MODELS FOR MANAGING TECHNOLOGY CHANGE AND A COMPARISON TO A RADIO FREQUENCY IDENTIFICATION IMPLEMENTATION M.S. Thesis
Mark S. Reboulet and Phillip L. Robinson Sep. 1993 137 p
(AD-A276012; AFIT/GLM/LA/93S-36) Avail: CASI HC A07/MF A02

This research developed an aggregate model for technological implementation in organizations. The aggregate model drew information from various theoretical models and aggregated those elements that were common to several of the models. Those elements included: information availability, anticipated profitability, probability of success, user attitudes, political attitudes, external pressure, teamwork, strategic planning, resource availability, and training. Individuals involved at various organizational levels of a radio frequency identification implementation were interviewed to see if the aggregate model could be useful to managers. The researchers found evidence that each of the elements of the aggregate model could be beneficial to managers considering implementing new technologies. Also, the researchers found that individuals at different organizational levels tended to view these elements differently. Additionally, the researchers recommended several elements that could be added to the model. DTIC

ANALYSIS USING BI-SPECTRAL RELATED TECHNIQUE Final Report, 1 Oct. 1992 - 30 Sep. 1993
Ralph Hippenstiel 17 Nov. 1993 60 p
(AD-A276017; NPS-EC-93-020) Avail: CASI HC A04/MF A01

This report investigates the use of bispectral related techniques to extract detection / classification clues from time frequency representations. Earlier results have indicated that 1.5-D spectral techniques (a degenerate

version of the bispectrum) has potential signal to noise ratio (SNR) gain over conventional techniques. This is partially due to the rejection of Gaussian like perturbations by the cumulant based techniques. The third order moment for Gaussian zero mean random processes is essentially zero. It is assumed that the independence of the instantaneous power spectrum (IPS) from analytic signal representations and the Gaussian character of the noise causes minimal distortion of the output variables, hence permit signal characterization at low to moderate SNRs. The performance is demonstrated on synthetic signals and on segments of the NOSC data set. DTIC

WAVEFORM GENERATION FOR ULTRA-WIDEBAND RADAR SYSTEM M.S. Thesis
Hsiao-Feng Chiang Dec. 1993 86 p
(AD-A276352) Avail: CASI HC A05/MF A01

In the current literature, ultra-wideband (UWB) waveforms are said to possess several potential advantages such as penetration of foliage, walls and ground, as well as target identification and detection of stealth targets. Due to the potential advantages of UWB waveforms, UWB power sources are currently being developed. This thesis investigates the Fourier synthesis method of waveform generation which is to be used with ultra-wideband radar. The major advantages of this method over traditional methods are that accurate control of pulse shapes and pulse repetition intervals (PRI) can be generated. In this thesis, the Fourier method is extended to generation of binary coded waveforms for UWB systems. The generation of such codes is important as it allows for the use of longer coded pulses. These coded pulses contain more energy and improve signal to noise ratio (SNR) while still retaining the range resolution and other benefits of smaller pulse widths. DTIC

ELECTROMAGNETIC SCATTERING THROUGH LOADED APERTURE PANELS WITH NONZERO CONTACT IMPEDANCE Ph.D. Thesis - Univ. des Sciences et Techniques de Lille [DIFFRACTION ELECTROMAGNETIQUE A TRAVERS DES OUVERTURES CHARGEES PAR DES PANNEAUX DOTES D'UNE IMPEDANCE DE CONTACT NON NULLE]
Marc Sternberg 1993 214 p In FRENCH Original contains color illustrations
(ISSN 0078-3781)
(ONERA-NT-1993-2; ETN-94-96060) Avail: CASI HC A10/MF A03

Electromagnetic scattering through loaded apertures made of materials of finite conductivity (such as composite materials), which can be characterized by a surface impedance, is analyzed. These apertures consist of panels bound to an infinite, perfectly conductive plane by an interface of nonzero contact impedance. The case of panels that do not overlap with the surrounding structure is first treated, and the consequences of an evenly distributed contact impedance around the aperture are examined. The numerical results generated by a code based on the method of moments are compared with theoretical and experimental results. The effect of electrical contact through a set of points is studied, both numerically and experimentally. The effect of overlapping is investigated. A method for characterizing the quality of the contact between the panel and the metallic support is proposed. ESA

RADAR IMAGE CLASSIFICATION BY TEXTURE MEASUREMENTS Ph.D. Thesis - Paris 6 Univ. [CLASSIFICATION D'IMAGES DE RADAR PAR MESURES DE TEXTURE]
Anne Beaupere 1993 182 p In FRENCH Original contains color illustrations
(ISSN 0078-3781)
(ONERA-NT-1993-3; ETN-94-96061) Avail: CASI HC A09/MF A02

Radar image classification by texture analysis, (the spatial distribution of gray levels) as opposed to radiometric analysis, is addressed. It was demonstrated that although the statistical distributions of texture and speckle are different, the bias is generally very small and depends to a large extent on the surface observed. The results are used to classify the image in four major categories: water, urban areas, forest, and farmland. The classification results are interpreted by radar texture simulation. Two models that use the surface roughness and the alternation of shadows and reflective surfaces to develop an automatic radar image interpretation tool taking into account a wide diversity of ground models and texture signatures are proposed. This technique offers broad perspectives for both military and civil applications by supplying information that is often not visible to the naked eye. ESA

A MULTICHANNEL ARCHITECTURE FOR NAVAL TASK FORCE COMMUNICATION Final Report
William A. Thoet, Dennis J. Baker, and Dennis N. McGregor 30 Jan. 1994 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276230; NRL/FR/5520-94-9703) Avail: CASI HC A03

This report describes a new architecture for mobile, narrowband, broadcast radio networks, which is called the Multichannel Architecture (MCA). We compare the performance limits of an MCA network to a single-channel architecture based on an ideal handoff assigned multiple access (IHAMA) protocol. Both architectures have been proposed for Naval intratask force communications with HF and line-of-sight UHF radio. Formulas for the network load capacity for each architecture are derived for several important cases, and simulation results are presented for those cases where analytical results are not available. Based on equivalent equipment, the load capacity of MCA is shown to exceed that of IHAMA. MCA also outperformed IHAMA in other performance areas such as delay, the ability to handle voice and virtual circuits, and jam resistance. DTIC

LOW SIDELOBE REFLECTOR ANTENNA DESIGN FOR COMMUNICATIONS M.S. Thesis
Nelson A. Aramas 23 Sep. 1993 75 p
(AD-A276079) Avail: CASI HC A04/MF A01

The current antenna used in the Marine Radio AN/MRC-142 is a focal point fed reflector with a first sidelobe of -10 dB. A new antenna design is required with a sidelobe reduction of another 10 dB, and a minimum impact on the system upgrade cost. An improved feed consisting of a fed dipole and disk in the vicinity of a parasitic ring was designed for use with the current reflector. The disk acts as a ground plane for the dipole, with the ring narrowing the beamwidth, resulting in a stronger edge taper on the reflector. An existing computer code based on the the method of moments was used to compute the gain and the radiation pattern. Circular parabolic reflectors of 36 inches and 48 inches were analyzed. The results show that the 36 inch reflector cannot satisfy the conditions over the entire frequency band (1350 to 1850 MHz) simultaneously. The 48 inch reflector came very close to satisfying all the conditions, although the sidelobe level is off by approximately 2 dB at wide angles in the H-plane. DTIC

SEGMENT-BASED ACOUSTIC MODELS FOR CONTINUOUS SPEECH RECOGNITION Progress Report, 1 Oct. - 31 Dec. 1993
Mari Ostendorf and J. R. Rohlicek 11 Feb. 1994 12 p
(Contract N00014-92-J-1778)
(AD-A276109) Avail: CASI HC A03/MF A01

In work, we are interested in the problem of large vocabulary,

speaker-independent continuous speech recognition, and primarily in the acoustic modeling component of this problem. In developing acoustic models for speech recognition, we have conflicting goals. On one hand, the models should be robust to inter- and intra-speaker variability, to the use of a different vocabulary in recognition than in training, and to the effects of moderately noisy environments. In order to accomplish this, we need to model gross features and global trends. On the other hand, the models must be sensitive and detailed enough to detect fine acoustic differences between similar words in a large vocabulary task. To answer these opposing demands requires improvements in acoustic modeling at several levels: the frame level (e.g. signal processing), the phoneme level (e.g. modeling feature dynamics), and the utterance level (e.g. defining a structural context for representing the intra-utterance dependence across phonemes). This project address the problem of acoustic modeling specifically focusing on modeling at the segment level and above. DTIC

MULTIPLE SCATTERING OF POLARIZED RADIATION IN PLANETARY ATMOSPHERES Ph.D. Thesis

Willem Maria Frans Wauben 1992 187 p

(ETN-94-96018) Avail: CASI HC A09/MF A02

Multiple scattering of polarized radiation in planetary atmospheres is addressed in studies of calculation methods for observations of the reflected sunlight and the internal radiation field, which give information on the constituents and the vertical structure of planetary atmospheres. An adding/doubling method and other computational methods which give insight into the general behavior of the polarized radiation in planetary atmospheres are considered. The relationship between the single scattering characteristics and the polarized radiation in optically thin atmospheres is shown. The main characteristics of the radiation in optically thick atmospheres can be explained by using asymptotic expressions. The main differences between the polarized radiation in atmospheres of intermediate optical thickness, but containing different particles, are explained by using the first order radiation and asymptotic expressions. An approximative method shows the variation of the polarized radiation near the boundaries of the atmosphere. Observations of radiation scattered in the atmosphere of Venus are investigated. It is shown that the main features of the observed internal intensities and fluxes as functions of altitude are described by a cloud/gas atmospheric model of Venus. Pioneer Venus polarimetric data are analyzed by using a cloud/haze model. It is found that at a wavelength of 0.935 micrometers the observations can be explained in terms of this cloud/haze model, but that the agreement is less satisfactory at shorter wavelengths. Thus, the polarization observations at these shorter wavelengths may contain information that can be used for a further refinement of the atmospheric model. ESA

SPECTRAL ANALYSIS METHOD AND SAMPLE GENERATION FOR REAL TIME VISUALIZATION OF SPEECH Ph.D. Thesis [VERFAHREN DER SPEKTRALANALYSE UND MUSTERGENERIERUNG FUER DIE REALZEITVISUALISIERUNG GESPROCHENER SPRACHE]

Klaus Hobohm 1993 194 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-94-95732) Avail: CASI HC A09

A method for translating speech signals into optical models, characterized by high sound discrimination and learnability and designed to provide to deaf persons a feedback towards control of their way of speaking, is presented. Important properties of speech production and perception processes and organs involved in these mechanisms are recalled in order to define requirements for speech visualization. It is established that the spectral representation of time, frequency and amplitude resolution of hearing must be fair and continuous variations of acoustic parameters of speech signal must be depicted by a continuous variation of images. A color table was developed for dynamic illustration and sonograms were generated with five spectral analysis methods such as Fourier transformations and linear prediction coding. For evaluating sonogram quality, test persons had to recognize consonant/vocal/consonant words and an optimized analysis method was achieved with a fast Fourier transformation and a postprocessor. A hardware concept of a real time speech visualization system, based on multiprocessor technology in a personal computer, is presented. ESA

STRUCTURE ESTIMATION OF PHASE OBJECTS FROM THE DIFFRACTION NEAR FIELD: MICROWAVE AND MODEL CALCULATIONS Ph.D. Thesis [STRUKTURBESTIMMUNG VON PHASENOBJEKTEN AUS DEM BEUGUNGSNAHFELD: MIKROWELLENMESSUNGEN UND MODELLRECHNUNGEN]

Marco Alexander Krumbuegel 1993 176 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-94-95737) Avail: Issuing Activity (European Space Agency (ESA))

The diffraction near field behind big, flat plate phase objects with wedge angles between 30 and 150 degrees are examined with a modified Mach Zehnder interferometer for 3 cm microwaves, in order to allow amplitude and phase to be accurately and continuously measured with dependence on wave polarization. The uniform asymptotic theory, developed for nontransparent objects, was adapted to phase objects using a canonic transformation. A strong polarization dependent overestimation between theory and experiment is found, particularly when the electric field vector is perpendicular to object axis. A modification of the Born approximation was developed in order to apply scattering theory to dielectric objects, which allows the multiple scattering inside the object to be taken into account, using a complex transmission factor. Threshold and extreme values criteria for reconstruction of object data were developed, based on calculations with the method of moments and the new approximation and measured field distributions. It is shown that the wedge angle can be estimated from highness and position of wedge extreme values in case of low refractivity objects; it is found that the best method is the estimation of minima in spatial frequency spectrum. STUDY OF STRUCTURES OF DIFFERENT COMPLEXITY FOR THE COMMUNICATION BETWEEN TWO PROCESSORS Ph.D. Thesis [STRUKTURUNTERSUCHUNGEN VERSCHIEDENER KOMPLEXITAETSMASSE FUER DIE KOMMUNIKATION ZWISCHEN ZWEI PROZESSOREN]

Bernd Halstenberg 1991 78 p In GERMAN

(ETN-94-95750) Avail: CASI HC A05/MF A01

The structure of the complexity of communication between two processors was investigated. For functions defined on the Cartesian product of two finite sets the communication complexity is defined as the number of bits that have to be exchanged when two processors want to compute the function value and the input to each of them consists only of one component of the input pair. This definition is extended to nondeterministic and probabilistic models. Based on this definition for functions with a finite domain, non uniform complexity classes are defined. It is shown that the relations between these classes correspond to the polynomial time complexity classes for various Turing machine models in many aspects. On the other hand, certain pairs of classes are shown not to be equal; until now the corresponding inequalities are conjectured but unproved to hold for the polynomial time classes. ESA

A system that was developed to explore communication in virtual reality and which offers a simple and powerful method to embed verbal communication in simulations and visualizers by means of voice annotation is described. The prototype demonstrates that the addition of verbal communication opens up a range of new uses for virtual environments. A similar voice annotation facility is easily added to existing visualizers and simulations, and it enables reading, writing and communicating. ESA

APERTURE EXCITATION OF ELECTRICALLY LARGE, LOSSY CAVITIES

D. A. Hill, J. W. Adams, M. T. Ma, A. R. Ondrejka, and B. F. Riddle Sep. 1993 81 p
(PB94-145711; NIST/TN-1361) Avail: CASI HC A05/MF A01

The document presents a theory based on power balance for aperture excitation of electrically large, lossy cavities. The theory yields expressions for shielding effectiveness, cavity Q, and cavity time constant. In shielding effectiveness calculations, the incident field can be either a single plane wave or a uniformly random field to model reverberation chamber or random field illumination. The Q theory includes wall loss, absorption by lossy objects within the cavity, aperture leakage, and power received by antennas within the cavity. Extensive measurements of shielding effectiveness, cavity Q, and cavity time constant were made on a rectangular cavity, and good agreement with theory was obtained for frequencies from 1 to 18 GHz. THE DEVELOPMENT OF ACTIVE INTEGRATED ANTENNAS AND A DESIGN METHODOLOGY Ph.D. Thesis

David J. Roscoe Jun. 1993 189 p
(ISBN-0-315-86119-3; CTN-94-61184) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Active antennas permit the current distribution along the antenna structure to be altered in a controlled manner. A design methodology has been developed and verified as a useful engineering tool which allows for the analysis of an arbitrarily shaped active integrated travelling wave antenna. An electromagnetic based circuit simulator is used in conjunction with a post-processor to determine the current distribution and to calculate the radiation characteristics. In addition, a noise model has been developed and used to calculate the output temperature of active integrated traveling wave antennas. These tools have been verified experimentally, with good agreement between calculated and measured results. An active integrated antenna has been designed, modeled, fabricated, and verified experimentally. The structure is a series distribution of microstrip transmission line and amplifiers. This antenna possesses numerous characteristics unachievable by traditional passive elements, but some undesirable traits such as poor noise temperature performance have been identified. Some applications of this type of active antenna are presented, including active element phased arrays. Author (CISTI)

LINEARLY SEPARABLE STACK-LIKE ARCHITECTURE FOR THE DESIGN OF WEIGHTED ORDER STATISTIC FILTERS WITH APPLICATION IN IMAGE PROCESSING M.S. Thesis

Christian Emanuel Savin Sep. 1993 100 p
(ISBN-0-315-87284-5; CTN-94-61238) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The problem of designing a weighted order statistic (WOS) filter for estimating a signal from its noise corrupted observation is considered. A new approach for WOS filter design is introduced by defining a more general type of filter configuration than the traditionally used linearly separable stack (LSS) filter design. The new type of filter architecture is characterized by a linearly separable Boolean function and is designated a linearly separable stacklike (LSSL) filter. It is shown that LSSL filters satisfy a new property called the generalized stacking property. Due to this property, the fundamentals of the optimality theory that have been developed for the class of stack filters remain valid in the framework of LSSL filters. It is shown that in the multilevel signal domain, a LSSL filter architecture performs the operation of WOS filtering. An adaptive algorithm for designing WOS filters in the domain of LSSL filter architecture is derived. An implementation of the proposed design algorithm is constructed using a binary level least mean squares algorithm. The proposed design and implementation is applied to the problem of restoring images corrupted with impulsive noise. Simulation results show that the WOS filters designed with the new method provide better results than those obtained using LSS filter architecture. Author (CISTI)

THE DEVELOPMENT AND TESTING OF A BACKSCATTER ABSORPTION GAS IMAGING (BAGI) SYSTEM DESIGNED TO IMAGE AT A RANGE OF 300 m

T. J. Kulp, R. Kennedy, M. Delong, D. Garvis, and J. Stahovec Apr. 1993 16 p Presented at the Society of Photo-Optical Instrumentation Engineers OE/Aerospace Science and Sensing Meeting, Orlando, FL, 11-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-006192; UCRL-JC-115032; CONF-930445-28) Avail: CASI HC A03/MF A01

The backscatter absorption gas imaging (BAGI) technique is a laser remote sensing method that fuses the chemical detection attributes of chemical lidar with the visualization capability of imaging laser radar (ladar) to allow real-time television images of invisible gas plumes to be made. The BAGI technique is carried out by actively imaging a scene with radiation having a wavelength absorbed by the gas to be visualized. Gas plumes present in the scene become visible in the image when they attenuate a portion of the backscattered radiation. Currently, all BAGI instruments that have been developed operate in the infrared (IR) and image gases via their fundamental vibrational transitions. The laser sources that have been used are the CO2 and the IR helium neon. The target range at which the current BAGI instruments are capable of operating varies between about 6 and 110 m. The imaging device used in those systems is an active raster-scanner that scans the beam of a continuous wave (C-W) laser and the instantaneous field-of-view (IFOV) of an infrared detector. In this paper, we summarize the design and preliminary performance evaluation of a new raster-scanning BAGI imager that is intended for long-range operation, at a target range of 300 m. A system capable of imaging at this range is desired to make airborne gas imaging from a low-flying airplane or helicopter possible. The system uses a 20 W CO2 laser and a redesigned scanner that employs telescopic transmission and receiving optics. Model predictions of the performance of the new system and some recent field testing results are presented. Issues relating to gas imaging at long ranges are also discussed. DOE

DISPERSION RELATIONS FOR A PLASMA-FILLED HELIX-LOADED-WAVEGUIDE

M. A. Makowski, E. B. Hooper, and B. W. Stallard Jan. 1994 23 p
(Contract W-7405-eng-48)
(DE94-006333; UCRL-ID-115969) Avail: CASI HC A03/MF A01

The propagation of waves on bounded, magnetized plasma columns arises in connection with a variety of applications. To this end, dispersion relations are developed for a variety of multi-region circularly symmetric configurations. These include the following: a sheath helix in free space; a plasma column in free space; a plasma filled conducting tube; a plasma filled sheath-helix in free space; a sheath helix within a conducting cylinder; a plasma filled sheath-helix within a conducting cylinder; and a plasma column within a sheath-helix contained within a conducting cylinder. The latter configuration is of the most interest for whistler wave excitation for plasma thruster applications, since it includes the effect of a vacuum region separating the plasma column from the helical excitation structure. (DE94-006404; UCRL-MA-115651) Avail: CASI HC A03/MF A01

Privacy Enhanced Mail (PEM) provides privacy enhancement services to users of Internet electronic mail. Confidentiality, authentication, message integrity, and non-repudiation of origin are provided by applying cryptographic measures to messages transferred between end systems by the Message Transfer System. PEM supports both symmetric and asymmetric key distribution. However, the prevalent implementation uses a public key certificate-based strategy, modeled after the X.509 directory authentication framework. This scheme provides an infrastructure compatible with X.509. According to RFC 1422, public key certificates can be stored in directory servers, transmitted via non-secure message exchanges, or distributed via other means. Directory services provide a specialized distributed database for OSI applications. The directory contains information about objects and then provides structured mechanisms for accessing that information. Since directory services are not widely available now, a good approach is to manage certificates in a centralized certificate server. This document describes the detailed design of a centralized certificate cache serve. This server manages a cache of certificates and a cache of Certificate Revocation Lists (CRL's) for PEM applications. PEMapplications contact the server to obtain/store certificates and CRL's. The server software is programmed in C and ELROS. To use this server, ISODE has to be configured and installed properly. The ISODE library 'libisode.a' has to be linked together with this library because ELROS uses the transport layer functions provided by 'libisode.a.' The X.500 DAP library that is included with the ELROS distribution has to be linked in also, since the server uses the DAP library functions to communicate with directory servers. DOE

FRACTAL AND SPECTRAL ANALYSIS M.S. Thesis [ANALYSE FRACTALE ET SPECTRALE]
Marko Lemieux Dec. 1992 140 p In FRENCH
(ISBN-0-315-86460-5; CTN-94-61199) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The fractal dimension of noise can be evaluated with the aid of classical methods borrowed from fractal analysis. Nevertheless, these methods are generally incompatible with spectral analysis processes. A study is presented of a method for calculating the dimension of a signal based on its amplitude spectrum. In effect, the slope determined by the principal coefficients of a discrete spectrum is a function of the fractal dimension of the corresponding signal. The maxima spectrum method combines low pass filtering, a large window of analysis, and linear regression. This technique requires a good mastery of the fast Fourier transform. As an application, comparative trials were performed on various signals with the above method and two other methods derived from fractal analysis. The results obtained are similar to those from classical methods of fractal analysis while the signal is pure or complex and if the frequency distribution is known. Nevertheless, the proposed technique fails if the distribution is unknown, as is the case with complex signals obtained from sums of pure noise originating from different families. CISTI

HIGH-RESOLUTION SYNTHETIC APERTURE RADAR OBSERVATIONS OF THE MOON Ph.D. Thesis
Nicholas John Sholto Stacy 1993 224 p
Avail: Univ. Microfilms Order No. DA9319369

Variations in radar backscatter from planetary surfaces are related to differences in the local slope and the electrical and structural properties of the top surface layer. The top few meters of the surface of the moon consist of fine-grained unconsolidated rock material containing exposed and buried rocks. Previous lunar radar measurements have shown a depolarized backscatter component related to the abundance of surface and subsurface rocks and a linearly polarized component associated with subsurface backscatter. High spatial resolution observations of the lunar surface were conducted using the Arecibo Observatory 12.6 cm wavelength radar in 1990 and 1992 with the aim of analyzing local variations in the surface backscatter properties. In the finest spatial resolution mode, a pulsed pseudo-random code with a 10 MHz bandwidth was transmitted and approximately 24 minutes of data was processed to achieve pixel resolutions smaller than 40 m in both dimensions. To obtain this fine resolution over a large area, a focused delay-Doppler algorithm was developed. This new data processing method applies range and frequency offsets to the raw data that permit processing with an algorithm similar to that used for strip mode synthetic aperture radar. A circularly polarized wave was transmitted and both senses of circular polarization were received. Stokes vector analysis was used to estimate the circularly and linearly polarized backscatter components. The comparison of these measurements to a model of quasi-specular and diffuse backscatter from surface and subsurface structures yielded estimates of the surface dielectric constant and showed that subsurface quasi-specular scattering is required for this model to explain the linearly polarized backscatter power. Images of the lunar poles show enhanced backscatter with a circular polarization ratio of approximately 0.9 from the radar facing inner walls and ejecta of several impact craters. This result is mainly attributed to diffuse backscatter from exposed and buried rocks. The orientation of the linearly polarized backscatter component was found to correlate with surface topography confirming that this component is, in general, the result of transmission through the surface. Results of an interferometric experiment show that interferometric phase fringes related to topography can be generated from data acquired several months apart. Dissert. Abstr.

A representative sampling of meteor scatter propagation performance statistics is presented from the PL/GP High Latitude Meteor Scatter Test Bed. The data address questions of meteor scatter propagation under disturbed ionospheric conditions, as well as normal meteor scatter propagation in the polar region. The time and frequency variations of the propagation transfer function are characterized over the 35 to 147 MHz range, including the availability of useful meteor trails, the potential communication capacity associated with those trails, the occurrence and persistence of ionospheric scatter and sporadic E-layers, variations in the signal-to-noise ratios of each scatter return and the effects of auroral and polar cap absorption (PCA) events on meteor scatter propagation and communications. Statistics covering Arrival Rate, Duration, Duty Cycle, and Noise Temperature are presented. This bulletin is one of a series covering the test bed operation from February 1990 through September 1992. DTIC

Due to advances in different areas of microwave and millimeter-wave techniques, demand for efficient CAD tools has grown. This statement is today as true as it was at our last workshop held two years ago in Munich on this topic. The numerical analysis in time domain is attractive since it describes the evolution of physical quantities in a natural way. The two basic concepts, the modelling of fields and networks, are more closely related than it seems at first glance. In the TLM method, for example, the network model is the basis for modelling electromagnetic fields. Another example is the application of generalized S-matrix methods and diacoptics in field theory. The purpose of this conference is to stimulate synoptic considerations of field and network theory and to promote a lively exchange between researchers engaged in these fields. DTIC

The research consisted of two distinct but interrelated problems. First, the researchers performed the research necessary to establish and describe a set of metrics and theorems for Low Probability of Intercept Waveforms. This led to the development of a design and analysis methodology and capability for Low Probability of Intercept signals and systems. This methodology and capability resulted in an algorithmic approach to LPI design and is composed of two primary elements - an analytical-based, computer-aided system to evaluate the detectability of LPI waveforms, and computer simulation models which allow the LPI communication link to be simulated and evaluated against the effects of Jawing and intercept receivers. Secondly, as these tools were being developed, the researchers conducted basic research into the design of the next generation LPI waveforms and possible strategies for detecting them. The two research tasks were complementary effects. This research effort had elements of both basic and applied research. The theorems and metrics led to the development of a tool to analyze waveform detectability which will serve two functions. It can be used as a design instrument for the engineer who must select the most effective LPI modulation technique for a given system: and furthermore it can also be used to facilitate basic research in the area of waveform detectability. THE USE OF SERVICE LIMITS FOR EFFICIENT OPERATION OF MULTI-STATION SINGLE-MEDIUM COMMUNICATION SYSTEMS
S. C. Borst, O. J. Boxma, and H. Levy Jun. 1993 27 p Sponsored by Netherlands Organization for Applied Scientific Research TMO Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0924-0659)
(CWI-BS-R9312; ETN-94-96221) Copyright Avail: Issuing Activity (European Space Agency (ESA))

Time limits and service limits are the major mechanisms used for controlling a large variety of multistation single medium computer communication systems like the Token Ring and FDDI (Fiber Distributed Data Interface). The proper use of these mechanisms is still not understood and rules for efficient system operation are not available. A study aimed at the derivation of such rules is presented. A cyclic polling model with different service limits (k-limited service) at the different queues is used. Interest is in determining these k-limit values so as to minimize the mean waiting cost of messages in the system. A simple approximative approach is proposed for two major problems: one in which a limit is set on the token rotation time and one in which no limits are imposed. The approach is tested for a variety of cases and is shown to be very effective. ESA

As part of an ongoing effort to determine the utility of ultra-wideband (UWB) radar systems for military application, an experimental program was developed and executed to collect terrain clutter data using high resolution waveforms in the ultra high frequency (UHF) spectral region. Two approaches to the design of the radar instrumentation to be used to collect these data were considered: an impulse system with a nominal 1 ns pulse duration and a conventional stepped-chirp instrumentation radar covering the same frequency range. A novel feature of the program was the use of a scanned linear aperture to simulate the use of a large, ideally weighted real aperture antenna system. In this paper, the theoretical analysis done to predict and compare the performance expected from either system approach is presented in terms of the noise-equivalent reflectivity of the clutter measurement system, the time to collect data, and the impact of the linearly scanned aperture on sensitivity, angular resolution, and data collection time. The Integrated Tiger Series (ITS) is a powerful, but user-friendly, software package permitting state-of-the-art modelling of electron and/or photon radiation effects. The programs provide Monte Carlo solutions for linear time-independent coupled electron/photon radiation transport problems, with or without the presence of macroscopic electric and magnetic fields. The ITS system combines operational simplicity and physical accuracy in order to provide experimentalist and theorists alike with a method for the routine but rigorous solution of sophisticated radiation transport problems. ELECTRONIC MAIL AND ORGANIZATIONAL KNOWLEDGE: MEDIA USE IN A GLOBAL CORPORATION
Robert E. Kraut and Paul Attewell Dec. 1993 20 p
(AD-A276707; CMU-CS-93-208) Avail: CASI HC A03/MF A01

Several attributes of communication media influence the costs of their use and utility, and these in turn have the potential to influence their patterns of use and organizational consequences. The goal of this paper is to examine some of these media attributes and their consequences in a large international firm. The data come from a survey of 973 employees of a multi-national corporation. They show that the distinguishing attributes of different media are not dominant: people whose jobs require substantial communication are likely to communicate heavily using all media available to them. The best predictor of which medium is used is the extent to which the medium can put people into contact with their important communication partners. When the job is the unit of analysis, the data from this survey do not support the media richness hypothesis - that use is determined by the fit between the richness of a medium and the degree to which people have complex, ambiguous, or social jobs. Yet when one takes a single conversation as a unit of analysis, the data show that media differing in interactivity and expressiveness are valuable for different tasks. Employees who use electronic mail extensively are better informed about their company and more committed to its management's goals. One reason for their superior knowledge about the organization seems to be that electronic mail promotes 'information spillover' from a focal recipient to others less directly interested in a message, without subjecting these marginal parties to the burdens of interruption and information overload. ELECTROMAGNETIC WAVE REFLECTION FROM IRREGULAR PLASMA LAYERS Final Report, 31 Aug. 1989 - 2 Sep. 1993
Dennis Papadopoulos, Ramy Shanny, and Robert D. Short 31 Aug. 1993 34 p
(Contract F19628-89-C-0174)
(AD-A276727; AD-E201774; PL-TR-93-2204) Avail: CASI HC A03/MF A01

The general theory describing reflection of electromagnetic waves from irregular reflectors was formulated by using path integral techniques (Dashen, 1979; Flatte, 1979). The general formulae reproduce the well known reflection coefficients for wave scattering from random rough surfaces derived by using Kirchhoff's theory or perturbation theory (Ogilvie, 1991). The theory was used to determine the degradation of an OTH radar signal scattered from irregular Artificial Ionospheric Mirrors (AIM). The cases of density irregularities induced by fluctuations in the ambient neutral density and by fluctuations in the heater power were separately examined. Scaling laws and bounds for minimal signal loss were derived. DTIC

DEVELOPMENT OF A FREQUENCY-DOMAIN ELECTROMAGNETIC SCATTERING MEASUREMENT SYSTEM M.S. Thesis
Kenneth K. Oh Dec. 1993 74 p
(AD-A276738) Avail: CASI HC A04/MF A01

This thesis describes the development of a system for measuring frequency-domain scattered fields in the Transient Electromagnetic Scattering Range at the Naval Postgraduate School. The new system employs a stepped-frequency CW waveform and utilizes an HP-8510B network analyzer as an RF front-end and a coherent receiver. A pair of AEL H1498 antennas was installed to cover a frequency range of 2 GHz to 18 GHz. An HP-82300C BASIC Language Processor was installed on a COMPAQ Deskpro-386 PC, and an HP-BASIC program was developed for remote control of the HP-8510B with data acquisition over the HPIB bus. A post-processing algorithm was created using MatLab for background subtraction, calibration, and deconvolution. A set of RCS measurements was made using various size spheres, and the postprocessing outputs were compared to computed values. Good agreement between these measurements and computed data indicates excellent accuracy of the measurement system and valid operations of the postprocessing algorithm. DTIC

HIGH-PERFORMANCE SPEECH RECOGNITION USING CONSISTENCY MODELING Technical Report, 4 Aug. 1992 - 4 Aug. 1993
Vassilios Digilakis, Peter Monaco, Hy Murveit, and Mitchel Weintraub Mar. 1994 11 p
(AD-A276775) Avail: CASI HC A03/MF A01

The goal of this project conducted by SRI International (SRI) is to develop consistency modeling technology. Consistency modeling aims to reduce the number of improper independence assumptions used in traditional speech-recognition algorithms so that the resulting speech-recognition hypotheses are more self-consistent and, therefore, more accurate. Consistency is achieved by conditioning HMM output distributions on state and observations histories, P(x/s,H). The technical objective of the project is to find the proper form of the probability distribution, P; the proper history vector, H; the proper feature vector, x; and to develop the infrastructure (e.g. efficient estimation and search techniques) so that consistency modeling can be effectively used. During the first year of this effort, SRI focused on developing the appropriate base technologies for consistency modeling. We developed genonic hidden Markov model (HMM) technology, our choice for P above, and Progressive Search technology for HMM systems which allows us to develop and use complex HMM formulations in an efficient manner. Papers describing these two techniques are included in the appendix of this report and are briefly summarized below. This report also describes other accomplishments of Year 1 including the initial exploitation of discrete and continuous consistency modeling and the development of a scheme for efficiently computing Gaussian probabilities. USING TSAR WITH THE POST-PROCESSING FAR-FIELD OPTION
S. T. Pennock Oct. 1993 5 p
(Contract W-7405-eng-48)
(DE94-006615; UCRL-MA-115257) Avail: CASI HC A01/MF A01

The TSAR EM code has contained far-field projection algorithms for some time. One drawback to previous versions of TSAR has been the necessity to run the field advancement routines each and every time to generate far-field data. A change has been made to TSAR to allow tangential fields on the projection surface to be saved to a file. These fields can then be used with a new postprocessor, POSTFAR, to produce far-field points at any desired location without rerunning the field advancement portion of TSAR. This will save large amounts of time in producing far-field calculations and allow calculation of other test point locations. If the tangential field data is saved to an 8 mm tape, these calculations may be made at a much later date. DOE

DISCRETE-EVENT-DYNAMIC-SYSTEM-BASED APPROACHES FOR SCHEDULING TRANSMISSIONS IN MULTIHOP PACKET RADIO NETWORKS Annual Report, Oct. 1991 - Sep. 1992
Christos G. Cassandras 1993 4 p
(Contract N00014-91-J-2025)
(AD-A276566) Avail: CASI HC A01/MF A01

In the classic transmission scheduling problem, the nodes of a packed radio network (PRN) broadcast fixed-length packets over a common resource (the channel). Packet transmissions are subject to interference constraints; for example, if a node is transmitting a packet, then all adjacent (neighboring) nodes must refrain from transmission. One then adopts a slotted time model where every slot is allocated to a set of nodes which can simultaneously transmit without conflict. Thus, a node generally belongs to one or more of these sets (called transmission sets). Our approach is based on viewing the transmission scheduling problem as a single server multiclass polling problem with simultaneous resource possession. Here, a class corresponds to a transmission set. The server corresponds to a channel operating with deterministic service times: a service time is equal to one time slot required for transmitting a packet. The scheduling problem is then equivalent to assigning the server (equivalently, each time slot) to a particular transmissions set. The simultaneous resource possession feature arises because the server is assigned to a transmission set, i.e. it can simultaneously provide service to packets from all nodes which belong to that set. The construction of the transmission set is dependent upon the topology and connectivity of the PRN and is equivalent to a graph partitioning problem. For our purposes, we assume M transmission sets have been specified. Finally, we allow for overlapping transmission sets, i.e. a node can belong to two or more difference transmission sets. DTIC

ATMOSPHERIC PROPAGATION EFFECTS THROUGH NATURAL AND MAN-MADE OBSCURANTS FOR VISIBLE TO MM-WAVE RADIATION [LES EFFETS DES CONDITIONS DEFAVORABLES DE PROPAGATION SUR LES SYSTEMES OPTIQUES, IR ET A ONDES MILLIMETIQUES]
Nov. 1993 209 p In FRENCH Presented at the Electromagnetic Wave Propagation Panel Symposium, Palma de Mallorca, Spain, 17-20 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276919; AGARD-CP-542; ISBN-92-835-0727-4) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Modern, precision-guided weapons require that guidance and target acquisition/recognition systems take into account the effects of the propagation environment. Successful performance must be obtained under adverse weather conditions such as haze, clouds, fog, rain, and snow and under adverse battlefield conditions such as dust, smoke, and man-made obscurants. Sensors operate at wavelengths ranging across the millimeter, IR, and the visible regions of the electromagnetic spectrum. Propagation effects vary drastically over this wavelength span and systems may employ a combination of sensors to mitigate adverse environmental conditions. The effectiveness of countermeasures such as multispectral obscurants and multispectral camouflage also depends on atmospheric properties. System performance is measured in terms of probability of detection, probability of recognition, and, ultimately, in terms of probability of a kill. A partial listing of the processes that affect theses probabilities and, in turn, are affected by the propagation environment includes extinction, angles and amplitude scintillation, target to background contrast, contrast transmission, and clutter characteristics. The symposium addresses the following topics: natural obscurants, multispectral camouflage, man-made obscurants and battlefield-induced phenomena, and target and background signatures. DTIC

LOW ALTITUDE NEAR-THE-HORIZON PROPAGATION: A COMPARISON BETWEEN RPO AND M-LAYER M.S. Thesis
Chi-Wei Wu Dec. 1993 140 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277358; NPS-EC-93-022) Avail: CASI HC A07

Predictions of propagation loss made by the computer programs Radio Physical Optics (RPO) Computer Software Configuration Item (CSCI) and M-Layer are compared. The results of the high frequency parabolic equation approximation, as formulated in RPO, agree almost always with those derived from the low frequency modal computation as formulated in M-Layer. But at low altitudes in the neighborhood of the radar horizon, deviations between RPO and M-Layer become significant for some cases. RPO appears not to be able to properly account for the effects of a high altitude surface-based duct at a short range. Since the discrepancies fall in regions of importance to naval operations, a definitive resolution is an urgent task to be undertaken in the immediate future. DTIC

DESIGN, DEVELOPMENT, AND TESTING OF A NETWORK FREQUENCY SELECTION SERVICE (NFSS) Final Report
Dennis J. Baker and Jastej Dhingra 14 Feb. 1994 195 p
(AD-A277362; NRL/MR/5520-94-7442) Avail: CASI HC A09/MF A03

This report focuses on the design, development, and testing of a prototype Network Frequency Selection Service (NFSS) that would automate the selection of a single, best frequency for operation of a single-channel network. After selecting the operating frequency, the NFSS proceeds to set the client network's transmitter and receiver to the chosen frequency. The NFSS is intended to be used as a scheduled service. During the periods when the NFSS is active, it normally tests a subset of the candidate frequencies, along with the previously chosen best frequency, and chooses the new best frequency from among this subset. Eventually, over several such active periods, all candidate frequencies are tested. The client network operates in its normal manner between activations of the NFSS. In the prototype NFSS, the 'best' frequency is the one that minimizes the frequency selection metric, which contains in order of importance: the number of relay nodes disconnected from the main body of the network, the number of relay nodes needed to form a backbone network, the number of links that the given topology falls short of being a fully connected network, and the index of the frequency in the sequential collection of candidate frequencies. A representative sampling of meteor scatter propagation performance statistics is presented from the PL/GP High Latitude Meteor Scatter Test Bed (HLMSTB). The data address questions of meteor scatter propagation under disturbed ionospheric conditions, as well as normal meteor scatter propagation in the polar region. The time and frequency variations of the propagation transfer function are characterized over the 35 to 147 MHz range, including the availability of useful meteor trails, the potential communication capacity associated with those trails, the occurrence and persistence of ionospheric scatter and sporadic E-layers, variations in the signal to noise ratios of each scatter return, and the effects of auroral and polar cap absorption (PCA) events on meteor scatter propagation and communications. Statistics covering arrival rate, duration, duty cycle, and noise temperature are presented. This bulletin is one of a series of polar meteor scatter data bulletins. DTIC

COMMUNICATION NETWORKS FOR AUTONOMOUS MOBILE ROBOT COMPUTER ARCHITECTURES AND DISTRIBUTED REAL-TIME COMPUTING Ph.D. Thesis
Caglan Mehmet Aras 1993 137 p
Avail: Univ. Microfilms Order No. DA9316600

Communication networks play an increasingly important role in many areas of computing. This dissertation introduces an interprocessor communication network for mobile robot computer architectures and real-time communication networks for distributed real-time computing. In both cases, the objective of the research is to provide communication with very low delay. Mobile robot tasks such as collision avoidance and dynamic navigation change over time and exhibit a high degree of cooperation. The segmented bus is a reconfigurable interconnection network for intelligent mobile robot applications. The segmented bus employs a preemptive circuit-switched message transfer technique for low delay. For mobile robot applications, analysis suggests that message delays are lower on the segmented bus as compared to alternatives such as the multiple bus. Interactive real-time message streams are used in continuous media distributed sensing and command/control applications. These streams require low end-to-end delay bounds and zero-loss. This dissertation offers solutions to message-stream admission and low latency message transfers for interactive real-time message streams on communication networks. The proposed adaptive stream admission procedure is shown to admit more streams to a network

than previous approaches. The proposed preemphasis cut-through data transfer mechanism reduces the minimum achievable end-to-end delay bound of a packet-switched network to values approaching circuit-switched techniques. To obtain low latencies on integrated broadband networks, the asynchronous transfer mode (ATM) must support bound-delay, zero-loss data transfers. A message-level delay control mechanism based on preemptive cut-through is presented. Hardware and software to implement message-level delay control are described results show a significant reduction in computation requirements when message-level delay control is used on ATM switch processors. ADVANCED SATELLITE COMMUNICATION SYSTEM Final Report
Edward J. Staples and Sen Lie May 1992 92 p
(Contract NAS3-25862; SBIR-14.05-9388)
(NASA-CR-194211; NAS 1.26:194211) Avail: CASI HC A05/MF A01

The objective of this research program was to develop an innovative advanced satellite receiver/demodulator utilizing surface acoustic wave (SAW) chirp transform processor and coherent BPSK demodulation. The algorithm of this SAW chirp Fourier transformer is of the Convolve - Multiply - Convolve (CMC) type, utilizing off-the-shelf reflective array compressor (RAC) chirp filters. This satellite receiver, if fully developed, was intended to be used as an on-board multichannel communications repeater. The Advanced Communications Receiver consists of four units: (1) CMC processor, (2) single sideband modulator, (3) demodulator, and (4) chirp waveform generator and individual channel processors. The input signal is composed of multiple user transmission frequencies operating independently from remotely located ground terminals. This signal is Fourier transformed by the CMC Processor into a unique time slot for each user frequency. The CMC processor is driven by a waveform generator through a single sideband (SSB) modulator. The output of the coherent demodulator is composed of positive and negative pulses, which are the envelopes of the chirp transform processor output. These pulses correspond to the data symbols. Following the demodulator, a logic circuit reconstructs the pulses into data, which are subsequently differentially decoded to form the transmitted data. The coherent demodulation and detection of BPSK signals derived from a CMC chirp transform processor were experimentally demonstrated and bit error rate (BER) testing was performed. To assess the feasibility of such advanced receiver, the results were compared with the theoretical analysis and plotted for an average BER as a function of signal-to-noise ratio. Another goal of this SBIR program was the development of a commercial product. The commercial product developed was an arbitrary waveform generator. The successful sales have begun with the delivery of the first arbitrary waveform generator. Derived from text

HIGH PEAK POWER MICROWAVES: A HEALTH HAZARD Final Report, 1 Aug. - 31 Dec. 1992
Henry A. Kues 1 Dec. 1993 101 p Prepared in cooperation with Wilmer Ophthalmological Inst., Baltimore, MD
(Contract MIPR-92MM2600)
(AD-A277168) Avail: CASI HC A06/MF A02

Prior research has established the ability of microwave exposure to produce a variety of biological effects including ocular changes. Investigations in our laboratory have demonstrated corneal endothelial lesions, increased vascular permeability, electroretinographic changes, and structural damage. The present study was designed to verify previous results using high-peak-power pulsed microwave exposure (1.25 GHz, 1 MW peak power, 1 or 16 Hz, and pulse duration of 0.5 or 10 microns) and to determine the extent of ocular damage. For this study we employed the rhesus monkey (Macaca mulatta) whose ocular anatomy and physiology is very similar to the human eye. Each subject was given a battery of clinical diagnostic tests prior to exposure and again following completion of all exposures. Each restrained subject was exposed for 4 hours, on three consecutive days over a three week period. Although some tests such as routine slit lamp examination failed to show any changes, both ERG and histopathology documented significant microwave induced retinal alteration. These results document the ability of high-peak-power pulsed microwaves to result in clinically significant ocular changes. The effects observed in this study demonstrate that under certain exposure conditions microwaves could present a human health hazard. DTIC

SYSTEM FOR MONITORING AND ANALYZING FIELD ENERGY EXPOSURE Patent Application
John F. Scarzello, inventor (to Navy), Adam C. Feaga, inventor (to Navy), and Daniel S. Lenko, inventor (to Navy) 6 Dec. 1993 30 p
(AD-D016115; US-Patent-Appl-SN-186711; Navy-Case-75176) Avail: CASI HC A03/MF A01

A portable electromagnetic field exposure dosimeter includes a triaxial ferrite-loaded coil sensor, a group of amplifiers and bandpass filters, a data control board, and a computer. The triaxial sensor receives electromagnetic radiation along three orthogonal axes for measurement which is channeled through a group of amplifiers and then bandpass filtered into three frequency signal ranges. One frequency range corresponds to exposure at 60 Hz and two of its harmonics. The second frequency range corresponds to high frequency pulsed energy. The third frequency range reflects body motion of a tested individual. The data control board converts such filtered signals into digital code and controls the flow of the converted data to random access memory and to the computer. The computer performs a Fast Fourier Transform on the converted data from the 60 Hz frequency range and then stores or displays the analyzed data as a function of frequency and time. The computer also stores or displays the data from the other two frequency ranges. DTIC

ANALYSIS OF DIETZ'S SINGLE, RECTANGULAR PULSE THEORY FOR THE GENERATION OF RADIATION VIA PHOTOELECTRONS
T. M. Dipp Dec. 1993 57 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-006131; LA-12629-MS) Avail: Issuing Activity (Department of Energy (DOE))

The generation of radiation via photoelectrons induced off of a conducting surface has been analytically modeled and computationally simulated by several researchers. This paper analyzes and compares Dietz's theory predictions with my research to form a unified foundation of consistent, inter-supporting results that should provide confidence in the independently performed basic research and resulting scaling laws and predictions. In doing so, this paper concentrated on Dietz's small-spot, single, rectangular, 'weak' pulse theory and equations, which involve nonrelativistic, monoenergetic photoelectrons emitted normal to a conducting surface in vacuum. In this paper I: (1) analytically compare Dietz's theory equations with my theory equations, (2) compare Dietz's theoretical scaling laws with my Particle-In-Cell (PIC) code simulation results, and (3) make Dietz's equations easier to use in predicting and optimizing photoelectron-generated radiation. As a result, it is shown that Dietz's equations match my theory's equations in their predicted scaling laws, differing only slightly in their coefficients and unique model parameters. Also, Dietz's equations generally agree with the PIC code results. Finally, optimization analysis showed that theoretical conversion efficiencies for typical real metals can meet and exceed values of 10(exp -5) if optimal photon energies of 15 to 20 eV are used. Even better efficiencies should be possible if the small-spot constraint is violated as well. DOE

ETHICS AND RATIONALITY IN INFORMATION-ENRICHED DECISIONS: A MODEL FOR TECHNICAL COMMUNICATION
S. B. Dressel, P. Carlson, and M. J. Killingsworth 1993 5 p Presented at the 41st Annual Conference of the Society for Technical Communication, Minneapolis, MN, May 1994
(Contract W-7405-eng-36)
(DE93-040251; LA-UR-93-2864; CONF-940534-2) Avail: CASI HC A01/MF A01

In a technological culture, information has a crucial impact upon decisions, but exactly how information plays into decisions is not always clear. Decisions that are effective, efficient, and ethical must be rational. That is, we must be able to determine and present good reasons for our actions. The topic in this paper is how information relates to good reasons and thereby affects the best decisions. A brief sketch of a model for decision-making, is presented which offers a synthesis of theoretical approaches to argument and to information analysis. Then the model is applied to a brief hypothetical case. The main purpose is to put the model before an interested audience in hopes of stimulating discussion and further research. DOE

COVICS: A COVERT VIDEO COMMUNICATIONS SYSTEM
Roger Bracht and Tom Kuckertz 1994 11 p Presented at the Radio Frequency Expo West, San Jose, CA, 23 Mar. 1994
(Contract W-7405-eng-36)
(DE94-007568; LA-UR-94-597; CONF-940378-1) Avail: CASI HC A03/MF A01 (US Sales Only)

A covert video communications system compatible with narrow band satellite use has been developed. The system communications by modulating reflected energy. This means that no energy is actively generated at the passive end of the link. Only the antenna is impedance is modulated to return the information. The recovered signal is then coherently demodulated to recover the information. The system uses microstrip antennas, operates at 10 GHz, and has a range of about 5 km. The video is slow scan and is updated every 2 seconds, and can be sent over a 2400 baud line such as is required for some satellite communications systems. A combination of discrete cosine transform and video differencing was used to achieve a high degree of video compression. DOE

LONG DISTANCE TRANSMISSION OF 15 Gb/s DIGITAL USING SUBCARRIER MULTIPLEXING AND EXTERNAL MODULATION
K. Hugenberg, M. Lowry, D. Beckedahl, and J. Blair Mar. 1994 9 p Presented at the DOD Fiber Optics Conference 1994, McLean, VA, 22-24 Mar. 1994
(Contract W-7405-eng-48)
(DE94-008298; UCRL-JC-115711; CONF-940363-3) Avail: CASI HC A02/MF A01

This paper provides an overview of a high-speed link design using subcarrier multiplexing techniques with external modulators. Although we have few experimental results to data, we feel the techniques and technology described in this paper will enable the simultaneous transmission of multichannel analog video and up to 15 Gb/s of digital data on a single wavelength. Furthermore, we show preliminary modeling that would indicate that at least four channels of 2.5 Gb/s can be sent over distances exceeding 500 km using a new dispersion technique that takes advantage of subcarrier multiplexing. DOE

MOM3D METHOD OF MOMENTS CODE THEORY MANUAL Final Report
John F. Shaeffer Mar. 1992 165 p Prepared for Lockheed Advanced Development Co., Sunland, CA
(Contract NAS1-18603; RTOP 505-69-30-01)
(NASA-CR-189594; NAS 1.26:189594) Avail: CASI HC A08/MF A02

MOM3D is a FORTRAN algorithm that solves Maxwell's equations as expressed via the electric field integral equation for the electromagnetic response of open or closed three dimensional surfaces modeled with triangle patches. Two joined triangles (couples) form the vector current unknowns for the surface. Boundary conditions are for perfectly conducting or resistive surfaces. The impedance matrix represents the fundamental electromagnetic interaction of the body with itself. A variety of electromagnetic analysis options are possible once the impedance matrix is computed including backscatter radar cross section (RCS), bistatic RCS, antenna pattern prediction for user specified body voltage excitation ports, RCS image projection showing RCS scattering center locations, surface currents excited on the body as induced by specified plane wave excitation, and near field computation for the electric field on or near the body. AN EXPLORATORY STUDY OF NEURO LINGUISTIC PROGRAMMING AND COMMUNICATION ANXIETY M.S. Thesis
Lois M. Brunner Dec. 1993 96 p
(AD-A277756) Avail: CASI HC A05/MF A01

This thesis is an exploratory study of Neuro-Linguistic Programming (NLP), and its capabilities to provide a technique or a composite technique that will reduce the anxiety associated with making an oral brief or presentation before a group, sometimes referred to as Communication Apprehension. The composite technique comes from NLP and Time Line Therapy, which is an extension to NLP. Student volunteers (17) from a Communications course given by the Administrative Sciences Department were taught this technique. For each volunteer, an informational oral presentation was made and videotaped before the training and another informational oral presentation made and videotaped following the training. The before and after training presentations for each individual volunteer were evaluated against criteria for communications anxiety and analyzed to determine if there was a noticeable reduction of anxiety after the training. Anxiety was reduced in all of the volunteers in this study. DTIC

HIGH FREQUENCE AND AUTOMATIC LINK ESTABLISHMENT (HF AND ALE) RADIO PROPAGATION TEST TO ANTARCTICA Final Report
P. E. Gilles, J. R. Katan, and B. L. Pease 1 Feb. 1994 194 p
(AD-A277730; NUWC-NPT-TR-10427) Avail: CASI HC A09/MF A03

Recent federal/military standards in the area of automatic link establishment (ALE) for HF radios have been developed that coordinate frequency selection between communicating terminals, allowing them to adapt to skywave conditions. This study focused on evaluating the utility of these state-of-the-art radios in the polar environment. A quick-look evaluation of this technology was demonstrated over a radio circuit between Christchurch, New Zealand, and McMurdo Station, Antarctica. This transauroral link, operated by the U.S. Navy for the National Science Foundation, is the primary link for all operational, logistical, and emergency communications for U.S. operations between the Antarctic and the outside world. Daily plots of the measured signal to noise ratio, probability of bit error, and channel quality are presented and analyzed. Because of the initial success of this technology demonstration, additional experiments were designed for deployment in FY 1993 to answer not only operational issues, but also to collect data for further scientific studies and engineering improvements. MULTICAST COMMUNICATION WITH GUARANTEED QUALITY OF SERVICE M.S. Thesis
Eric B. Boyer 16 Dec. 1993 103 p
(AD-A277650) Avail: CASI HC A06/MF A02

In this thesis, we address the problem of constructing multicast data distribution trees with guaranteed quality of service (QoS) for supporting multiparty interactions. We present an approach that integrates reservation with tree construction to facilitate a guaranteed quality of service. The proposed approach is based on the use of information about participants registered before the interaction starts. We first identify the design goals for multicast tree construction with minimum QoS requirements. We then describe a protocol to locate a set of distribution centers for an interaction

that depends upon the current load distribution, locations of the participants, and their QoS requirements. The protocol sets up a suitable number of center-specific trees for the interaction transparently. We compare the quality of the resulting trees on large, hypothetical networks with that of sender-specific and Steiner trees. Our results show that center-specific trees, built around the centers located by our approach, reserve fewer resources than sender-specific trees even for a significant number of simultaneous senders while sacrificing minimally in the average delay faced by each receiver. NOISE CANCELLATION FOR CELP VOICE ENCODERS IN AN F/A-18 NOISE ENVIRONMENT Interim Report, Jan. 1991 - Jan. 1993
David A. Heide 18 Mar. 1994 23 p
(AD-A277652; NRL/FR/5530-94-9712) Avail: CASI HC A03/MF A01

Because of the severe noise environment in the Navy's F/A-18 jet aircraft, it has always been very difficult to achieve highly intelligible speech using low data rate voice encoders such as the 2.4 kbps LPC-10. As a result, all voice encoding has been done with a high data rate 16.0 kbps CVSD algorithm. The main focus of this research was to develop a technique that could retain the acceptable intelligibility of the high rate encoders while still significantly lowering the data rate required. To achieve these results, a noise cancellation preprocessor was developed to be used in tandem with the new 4.8 kbps CELP encoder that is being implemented in the STU-3. While many noise reduction techniques were investigated, the best results were accomplished by first reducing the noise through spectral subtraction and then enhancing the important resonant formants of the speech. The results indicated that when the noise cancellation preprocessor was added to the CELP encoder, the DRT intelligibility scores were improved by a significant 5.0 points, making the speech much more acceptable for possible use in the F/A-18. AN EXPERIMENTAL COMPACT HI-VISION VCR USING METAL EVAPORATED TAPE
Koji Kamijo, Toshiyuki Matsui, and Kazutoshi Mutou Mar. 1994 17 p
(ISSN 0027-657X)
(NHK-Labs-Note-423) Copyright Avail: Issuing Activity (Japan Broadcasting Corp., Tokyo)

We studied VCR systems and made an experimental setup to design a Hi-Vision camera-VCR. We used a nonsegmented tape transport system, a TCI (time compressed integration) two-channel FM recording system, a lower shifting FM modulator, and a quadruple multiple FM demodulator with reduced Moire interference. The tape used a metal evaporated tape with superior recording ability in short wavelength areas. We realized high quality playback video signals from detailed analysis of the FM characteristics on a magnetic recording channel of the metal evaporated tape. The performances of this VCR are: the minimum recording wavelength of 0.37 micrometers, the baseband bandwidth of 20 MHz for luminance and 7 MHz for chrominance, and SNR of 41 dB for luminance and 45 dB for chrominance. THE 20 GHz CIRCULARLY POLARIZED, HIGH TEMPERATURE SUPERCONDUCTING MICROSTRIP ANTENNA ARRAY Final Report
Jarrett D. Morrow, Jeffery T. Williams, Stuart A. Long, and John C. Wolfe 31 May 1994 71 p
(Grant NAG9-593)
(NASA-CR-195097; NAS 1.26:195097; TR-94-13) Avail: CASI HC A04/MF A01

The primary goal was to design and characterize a four-element, 20 GHz, circularly polarized microstrip patch antenna fabricated from YBa2Cu3O(x) superconductor. The purpose is to support a high temperature superconductivity flight communications experiment between the space shuttle orbiter and the ACTS satellite. This study is intended to provide information into the design, construction, and feasibility of a circularly polarized superconducting 20 GHz downlink or cross-link antenna. We have demonstrated that significant gain improvements can be realized by using superconducting materials for large corporate fed array antennas. In addition, we have shown that when constructed from superconducting materials, the efficiency, and therefore the gain, of microstrip patches increases if the substrate is not so thick that the dominant loss mechanism for the patch is radiation into the surface waves of the conductor-backed substrate. We have considered two design configurations for a superconducting 20 GHz four-element circularly polarized microstrip antenna array. The first is the Huang array that uses properly oriented and phased linearly polarized microstrip patch elements to realize a circularly polarized pattern. The second is a gap-coupled array of circularly polarized elements. In this study we determined that although the Huang array operates well on low dielectric constant substrates, its performance becomes extremely sensitive to mismatches, interelement coupling, and design imperfections for substrates with high dielectric constants. For the gap-coupled microstrip array, we were able to fabricate and test circularly polarized elements and four-element arrays on LaAlO3 using sputtered copper films. These antennas were found to perform well, with relatively good circular polarization. In addition, we realized a four-element YBa2Cu3O(x) array of the same design and measured its pattern and gain relative to a room temperature copper array. The patterns were essentially the same as that for the copper array. The measured gain of the YBCO antenna was greater than that for the room temperature copper design at temperatures below 82K, reaching a value of 3.4 dB at the lowest temperatures. Author (revised)

DESIGN OF FREE SPACE INTERCONNECTED SIGNAL PROCESSOR Final Technical Report, Apr. 1991 - Feb. 1993
Miles Murdocca and Thomas Stone Dec. 1993 44 p
(Contract F30602-88-D-0028)
(AD-A278129; RL-TR-93-260) Avail: CASI HC A03/MF A01

Progress is described on a collaborative effort between the Photonics Center at Rome Laboratory (RL), Griffiss AFB and Rutgers University, through the RL Expert Science and Engineering (ES&E) program. The goal of the effort is to develop a prototype random access memory (RAM) that can be used in a signal processor for a computing model that consists of cascaded arrays of optical logic gates interconnected in free space with regular patterns. The effort involved the optical and architectural development of a cascadable optical logic system in which microlaser pumped S-SEED devices serve as logic gates. At the completion of the contract, two gate-level layouts of the module were completed which were created in collaboration with RL personnel. The basic layout of the optical system has been developed, and key components have been tested. The delayed delivery of microlaser arrays precluded completion of the processor during the contract period, but preliminary testing was made possible through the use of other microlaser devices. COASTAL BOUNDARY LAYER AND REFRACTIVITY MEASUREMENTS USING THE GROUND-BASED HIGH RESOLUTION INTERFEROMETER SOUNDER (GB-HIS) M.S. Thesis
Roy R. Ledesma Dec. 1993 81 p
(AD-A277980) Avail: CASI HC A05/MF A01

Timesections of potential temperature, dewpoint temperature, modified radar refractivity (M), and the vertical derivative of the modified radar refractivity (dM/dZ) from radiosondes and the Ground-based High Resolution Interferometer Sounder (GB-HIS) during three experiments are studied to analyze refractive effects in the coastal boundary layer and evaluate GB-HIS performance. In May of 1991 and 1992, the GB-HIS instrument was deployed on the Research Vessel Point Sur during research cruises off the central California coast. In August and September of 1993, the GB-HIS was deployed during the Variation of Coastal Atmospheric Refractivity (VOCAR) experiment at the Naval Air Station in Point Mugu, California. Comparisons of radiosonde observations with the GB-HIS is capable of depicting large-scale air mass changes in the coastal boundary layer with high temporal resolution. As a result, the general location of some refractive layers in the coastal boundary layer can be determined with the GB-HIS data. Small scale features in the moisture timesections from the raob data were not resolved by the GB-HIS with significant skill. The inability of the GB-HIS to capture the vertical moisture gradients seriously limits its ability to monitor refractive conditions. DTIC

AN ANALYSIS OF CELLULAR TELEPHONE AND INMARSAT SYSTEMS FOR PROVIDING RADIO DATA LINK COMPUTER COMMUNICATIONS FOR US NAVY VESSELS M.S. Thesis
David L. Cooper, Jr. Dec. 1993 69 p
(AD-A278143) Avail: CASI HC A04/MF A01

This thesis examines radio frequency data link computer communications systems with emphasis on their potential application to ship/shore communications. Covered are two systems that experts believe hold the most promise for DOD application, International Maritime Satellite (INMARSAT) and cellular radiotelephones. An analysis of system capabilities, cost, and future potential is performed for each, and then the two systems are compared. In addition, a thorough discussion of the security issues for each system and final conclusions/recommendations are presented. The conclusions suggest that increased cellular radiotelephone usage vice INMARSAT by fleet units would optimize fleet readiness and improve supply system performance. Based on these conclusions, this author's recommendation is that all Navy ships be equipped with a cellular telephone system, while all aircraft carriers and amphibious aircraft carriers be equipped with both cellular and INMARSAT systems. MILLSTONE HILL RADAR STUDIES OF PLASMA WAVES AND TURBULENCE Annual Report, Nov. 1992 - Oct. 1993
John C. Foster 15 Mar. 1994 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-1-0019)
(AD-A278409; AFOSR-94-0223TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Millstone Hill UHF radar was used as a diagnostic tool for investigating plasma waves and turbulence. During the 15-month interval covered by the first year of this award, experiments were performed using an alternating-code technique in order to assess this capability for use as a plasma diagnostic. Experiments at fixed antenna position and with real-time interaction investigated phenomena near perpendicular flow angle when looking very close to perpendicular magnetic aspect angle conditions. Analysis of prior data showed that when flow angle is varied through perpendicular while holding 0 degree aspect angle, an abrupt change in sign of the line of sight phase velocity is observed. Preparations were continued for bistatic coherent backscatter experiments in FY 94 using the MIDAS-C data acquisition system developed at Millstone Hill for use as a bistatic receiver in Canada. THE EFFECTS OF A MULTIPATH CHANNEL AND INTERFERENCE ON COHERENT M-PSK DIGITAL COMMUNICATION SYSTEMS Final Report, Oct. 1992 - Sep. 1993
R. C. North, R. A. Axford, and D. Bryan Nov. 1993 81 p
(ONR Proj. RC32W11)
(AD-A278158; NCCOSC/RDT/E-TR-1636) Avail: CASI HC A05/MF A01

This report derives expressions for the average probability of symbol error of coherent M-ary phase-shift-keyed (M-PSK) communication system operating under the following nonideal conditions: (1) time-invariant multipath channel consisting of a direct path and a single multipath, (2) intentional/unintentional interference consisting of either a continuous wave (CW) signal or a bandpass filtered white Gaussian noise signal (bandwidth is variable), and (3) additive white Gaussian noise. Exact solutions are derived for coherent binary phase shift-keyed (BPSK) while both exact and upper bound solutions (shown to be tighter than the Chernoff bound) are derived for coherent M-PSK. One particular example, line-of-sight ultrahigh frequency (LOS UHF) radio, is used extensively to exercise the derived expressions and illustrate typical system performance. These results pertain to receiver with no means of compensation for the nonideal channel conditions. Methods of compensation for multipath and interference, like adaptive equalization, beamforming, spatial diversity, and multichannel adaptive equalization, are presently under investigation by the authors. The results in this report will help determine the performance gain offered by these methods of compensation DTIC

GENERATION OF THE AMBIGUITY FUNCTION FOR ULTRA WIDEBAND RADAR WAVEFORMS M.S. Thesis
Efrain Leon Dec. 1993 84 p
(AD-A277913) Avail: CASI HC A05/MF A01

The Ambiguity Function is one of the tools used to study the suitability of waveforms for radar applications. An understanding of this function gives the radar engineer an insight into different radar waveforms and permits him to select the best design for a particular system application. This thesis investigates the Ambiguity Function for ultra wideband radar waveforms generated by the Fourier Synthesis Method, which provides the capability to produce very narrow pulses in a coherent and controllable form. Since, for ultra wideband radar waveforms, the transmitted signal is a baseband signal without sinusoidal carrier, the Ambiguity Function for this kind of waveform should be generated by Doppler processing in the time domain rather than in the frequency domain, as is done for conventional radar waveforms. In this thesis, the Ambiguity Function has been generated and analyzed for two different this wideband radar waveforms by means of computer simulation of a radar receiver which incorporates time-Doppler processing. ASSESSING THE VULNERABILITY OF MULTI-COMMODITY NETWORKS WITH FAILING COMPONENTS M.S. Thesis
Alan R. Robinsoln Mar. 1994 170 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278434; AFIT/GOR/ENS/94M-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research proposes an analytical approach for assessing flow disturbance, or 'compromise,' based on limited sampling of arc flow information in multicommodity, or multiple origin-destination (O-D), networks with failing arcs. There were three objectives established for this research. The first objective was to bound the expected flow, given the arcs fail with certain probabilities, which was accomplished by reviewing current approaches for single-commodity networks and extending the results to the multicommodity case. The second objective was to determine the best placement of flow monitors to obtain the most accurate estimates of O-D pair volumes. This was accomplished using a multicriteria approach for defining and evaluating all possible monitor placement strategies satisfying monitor availability. The O-D pair volumes were estimated using the l(sub p)-norm metric for varied levels of p. The final objective was to define a compromise metric providing confident assessments on the occurrence of 'compromise.' This was accomplished using simple regression techniques

to generate confidence intervals around the expected flow for each O-D pair. The approach proposed in this research is provided as an initial look into 'compromise' assessment based on limited network information.

PERFORMANCE STATISTICS BULLETIN. HIGH LATITUDE METEOR SCATTER PROPAGATION, JUNE, JULY, AUGUST, SEPTEMBER 1992 Interim Report
Alan D. Bailey, John M. Quinn, Patricia M. Bench, and Wayne I. Klemetti 2 Feb. 1994 268 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 4643)
(AD-A277508; AD-E201796; PL-TR-94-2026; ERP-1145) Avail: CASI HC A12

A representative sampling of meteor scatter propagation performance statistics is presented from the PL/GP High Latitude Meteor Scatter Test Bed. The data address questions of meteor scatter propagation under disturbed ionospheric conditions, as well as normal meteor scatter propagation in the polar region. The time and frequency variations of the propagation transfer function are characterized over the 35 to 147 MHz range, including the availability of useful meteor trails, the potential communication capacity associated with those trails, the occurrence and persistence of ionospheric scatter and sporadic E-layers, variations in the signal-to-noise ratios of each scatter return and the effects of auroral and polar cap absorption (PCA) events on meteor scatter propagation and communications. Statistics covering Arrival Rate, Duration, Duty Cycle, and Noise Temperature are presented. This bulletin is one of a series covering the test bed operation from February 1990 through September 1992.

APPLIED HARMONIC ANALYSIS Final Report, 1 Jan. 1989 - 31 Aug. 1993
Louis Auslander 31 Aug. 1993 4 p
(Contract F49620-89-C-0020)
(AD-A278384; AFOSR-94-0140TR) Avail: CASI HC A01/MF A01

Recent work by the CUNY group under the direction of Professor Louis Auslander has continued to study application of the Weil transform to radar signal processing and, in a parallel effort, to multi-access spread spectrum communications. The main thrust of the work is the relationship between the Weil transform of a waveform and the ambiguity surface of the wave-form. The study of this relationship has led to a fundamental observation: the cancellation properties of a waveform necessary for the creation of a thumbtack-like ambiguity surface may be viewed as arising from the pattern of zeros and the non-trivial winding numbers of the Weil transform of the waveform. This point of view is exposited and used to reinterpret classical radar waveform design techniques, while also providing a new method for radar waveform design. Additionally, a new technique for modifying or shaping waveforms has been developed. This consists of changing a waveforms has been developed. This consists of changing a waveform by multiplying its Weil transform by doubly-periodic functions and taking the inverse Weil transform to produce a new signal. DTIC

EXPERIMENTAL AND THEORETICAL STUDIES OF HYDROGENATED AMORPHOUS SEMICONDUCTOR ALLOYS AND SUPERLATTICES Final Report, 15 Sep. 1989 - 14 Dec. 1993
Zvi S. Weisz and Manuel Gomez 4 Feb. 1994 132 p
(Contract DAAL03-89-G-0114)
(AD-A276159; ARO-25715.6-MS-SAH) Avail: CASI HC A07/MF A02

We developed the photocarrier grating technique for carrier mobility-lifetime products (micro-Tau) measurements. Applying this technique to hydrogenated amorphous silicon (a-Si:H), we obtained micro-Tau values ranging from 10(exp -8) to 10(exp -5) sq cm/V for the majority and 10(exp -10) to 10(exp -8) for the minority carrier. This served as a basis for quality evaluation of differnt methods of preparation. We established that the dominant recombination mechanism is the 'defect pool' mechanism. Using the semiconductor-electrolyte system, we studied the density of localized states in a-Si:H and compared it to crystalline silicon. We found in a-Si:H an overall density of localized states in 10(exp -18)/cu cm. In crystalline Si only surface states were found, of an overall density of 10(exp -12) sq/cm. The sq cm states are centered around 0.2 eV the conduction band edge. The transport properties of two other disordered systems that may be relevant to a-Si:H were studied theoretically. These systems consist of metal cermets and of small colloidal suspensions. DTIC

HIGH-TEMPERATURE SUPERCONDUCTING TRANSFORMER PERFORMANCE, COST, AND MARKET EVALUATION
J. A. Dirks, J. E. Dagle, J. G. DeSteese, H. D. Huber, S. A. Smith, J. W. Currie, S. B. Merrick, and T. A. Williams Sep. 1993 204 p
(Contract DE-AC06-76RL-01830)
(DE94-005494; PNL-7318) Avail: CASI HC A10/MF A03

Recent laboratory breakthroughs in high-temperature superconducting (HTS) materials have stimulated both the scientific community and general public with questions regarding how these materials can be used in practical applications. While there are obvious benefits from using HTS materials (most notably the potential for reduced energy losses in the conductors), a number of issues (such as overall system energy losses, cost, and reliability) may limit applications of HTS equipment, even if the well known materials problems are solved. This study examined the future application potential of HTS materials to power transformers. This study effort was part of a U.S. Department of Energy (DOE) Office of Energy Storage and Distribution (OESD) research program, Superconductivity Technology for Electric Power Systems (STEPS). The study took a systems perspective to gain insights to help guide DOE in managing research designed to realize the vision of HTS applications. Specific objectives of the study were as follows: to develop an understanding of the fundamental HTS transformer design issues that can provide guidance for developing practical devices of interest to the electric utility industry; to identify electric utility requirements for HTS transformers and to evaluate the potential for developing a commercial market; to evaluate the market potential and national benefits for HTS transformers that could be achieved by a successful HTS development program; to develop an integrated systems analysis framework, which can be used to support R&D planning by DOE, by identifying how various HTS materials characteristics impact the performance, cost, and national benefits of the HTS application. A NEURON NETWORK FOR IMAGE CLASSIFICATION: FROM ALGORITHM TO IMPLANTATION Ph.D. Thesis [UN RESEAU DE NEURONES POUR LA CLASSIFICATION D'IMAGES: DE L'ALGORITHME A L'IMPLANTATION]
Anne Trotin 1993 170 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0751-1353)
(TELECOM-93-E-005; ETN-94-95898) Avail: CASI HC A08

The feasibility of implanting a neural network particular algorithm on a VLSI (Very Large Scale Integration) digital circuit is addressed. The target application is image recognition. The Neocognitron was used since it possesses particularly important tolerance capacities to image deformation in generalization phase, and a structure of local connections and shared weight which designates it as a good candidate for hardware integration. The general study of the model led to the carrying out of diverse transformations on the start algorithm in order to reduce the complexity of the operating phase processing. The learning was also modified, which allowed the size of different network layers to be automatically determined. The work was validated by simulations on a data base of postal code numerical manuscript extracts. The results obtained show that the simplifications carried out sometimes improve performances. The study of a digital integrated circuit allowed the complexity of the problem to be evaluated. It appears that the Neocognitron after modifications can be implanted. This nevertheless calls for the choice of a given application which allows an adapted structure to be defined. ESA

The study of elementary analog operators is addressed. Different techniques for 'transconductor' realization were studied, and architectures giving good linearity and low consumption were proposed. The transconductor study was applied to continuous time high frequency filtering. The design of Gm-C filters was studied. Nonlinear operators studied are: a CMOS multiplier, a family of nonlinear operators for neural network implementation. Mixed analog-digital operators allow operations between an analog signal and a digital signal. Potential applications of mixed operators are presented. ESA

VLSI IMPLEMENTATION OF STRAY INSENSITIVE SWITCHED CAPACITOR COMPOSITE OPERATIONAL AMPLIFIERS M.S. Thesis
Gregory A. Silvernagel Dec. 1993 127 p
(AD-A276461) Avail: CASI HC A07/MF A02

In this research, analog active circuits are implemented in VLSI technology by combining the properties of switched capacitors and composite amplifiers. This combined design improves upon the single operational amplifier's finite design, limited bandwidth, lower slew rate, as well as enhancing the overall network passive and active sensitivities. The switched capacitor is implemented using both the toggle switched capacitor and the modified open floating resistor techniques. The composite operational amplifier is implemented using the C20A-1 and C20A-2 designs from the CNOA-i possibilities. These four designs are produced on a single microchip that includes the two phase nonoverlapping clock circuit and the switches. The microchip is tested in a finite gain circuit and the results are used to evaluate the performance of the design. Shortcomings in the circuit performance are identified and the analysis is used to improve network simulations as well as provide guidance for design improvements. The design improvements are incorporated in a second generation microchip that is fabricated in a low noise analog process. DTIC

A SERIES RESONANT CONVERTER IN HALF BRIDGE CIRCUITS WITH COMBINED SERIAL AND PARALLEL CHARGE COUPLING AND SEVERAL OUTPUT CIRCUITS Ph.D. Thesis [EIN SERIENRESONANZUMRICHTER IN HALBBRUECKENSCHALTUNG MIT KOMBINIERTER SERIELLER UND PARALLELER LASTAUSKOPPLUNG UND MEHREREN AUSGANGSKREISEN]
Manfred Schlenk 1993 162 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95739) Avail: CASI HC A08

A method for dimensioning series oscillating circuit converters is described. The properties of oscillating circuits, quasiresonant and multiresonant converters were reviewed. Parallel power coupling is shown to provide lossless circuits, even with secondary converter discharge, but the efficiency is lower than with serial coupling. A combination of both couplings was proposed for operating the converter in nominal charge and voltage area. The ratio of parallel to serial resonance capacitors is shown to be dependent on converter maximal efficiency and natural frequencies of both oscillating circuits. The properties of control process for resonant converters are presented. The dimensioning of elementary values of the resonance circuit for a converter with serial/parallel charge coupling and ohmic charge is described. A calculation process was developed for voltages and currents in the secondary circuit. It is shown that the dynamic behavior of converters with several output circuits is strongly influenced by the coupling of output spools. ESA

THEORETICAL PRINCIPLES FOR DESIGNING LONG STATOR/LINEAR MOTORS WITH IRON Ph.D. Thesis [THEORETISCHE GRUNDLAGEN ZUR AUSLEGUNG VON EISENBEHAFTETEN LANGSTATOR-LINEARMOTOREN]
Rolf Hellinger 1993 153 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95741) Avail: CASI HC A08

Elements for dimensioning synchronous linear motors for rail transportation are presented. A calculation analytic method was developed, which is based on the introduction of the specific magnetic conductance function, which takes into account the influence of stator and excitation windings. Electromotive and inertia forces were estimated with the stator current function and the magnetic air gap flux density and the results were verified using the finite element method for solving Maxwell equations. The short circuit currents in the stator winding were evaluated by means of calculated inductivities. Some perturbations, such as sliding and oscillation forces were calculated. Some results were validated on the TRANSRAPID test vehicle. ESA

HIGH-PERFORMANCE GaAs/AlGaAs OPTICAL PHASE MODULATORS FOR MICROWAVE/PHOTONIC INTEGRATED CIRCUITS
V. M. Hietala, S. H. Kravitz, M. G. Armendariz, G. A. Vawter, R. F. Carson, and R. E. Leibenguth 1993 9 p Presented at the OE/LASE 1994 Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006361; SAND-93-1590C; CONF-940142-7) Avail: CASI HC A02/MF A01

High speed, high performance optical phase modulators are being developed for use in a coherent photonic integrated circuit (PIC) technology. These phase modulators are the critical component of a PIC program at Sandia National Laboratories targeted for microwave/millimeter wave signal processing and control including phased-array antenna control. The primary design goals for these modulators are amenability for integration into PICs, high 'figure of merit' (FOM: phase shift per unit length-voltage), and large bandwidths allowing for operation at millimeter wave frequencies. Depletion edge translation optical phase modulators (GaAs/AlGaAs based) have been selected as the device technology of choice due to their high FOM (greater than 60 deg/V-mm at 1.3 micron). These modulators unfortunately suffer from a large terminal capacitance which greatly limits speed. To overcome this problem, a distributed electrode design based on the use of slow-wave coplanar strips has been developed. Device design and measurements are presented. DOE

ANALYSIS OF KEY PERFORMANCE PARAMETERS OF PHASE SAMPLING DIGITAL RF MEMORIES Interim Report, 1 Jul. - 18 Nov. 1992
Mark D. Virden 21 Jan. 1994 15 p
(AD-A276019; NRL/FR/5742-94-9705) Avail: CASI HC A03/MF A01

This report explores several performance features of phase sampling digital RF memories (DRFM), starting with the phase sampling process itself. Spurious signal levels, bandwidth, and processing of simultaneous signals are analyzed using computer modeling of DRFM functions. The preferred phase sampling technique is to make phase comparisons between samples of the input signal and its 180 degree analog. The input amplifier and the noise immunity of the phase comparator determine the dynamic range. Theoretical spurious levels are tabulated for 2, 4, 8, and 16-state sampling. The data reveal no differences between two-state and four-state sampling. Other tables show output levels for simultaneous signals into eight-state and two-state DRFMS at different combinations of input amplitudes. The advantages of the phase DRFM are large bandwidth, large input signal dynamic range without automatic gain control, and the capability for direct output phase modulation. DTIC

A SILICON CONDENSER MICROPHONE: MODELLING AND ELECTRONIC CIRCUITRY Ph.D. Thesis
Armand Gijsbertus H. vanderDonk 1992 198 p
(ISBN-9-09-005279-8; ETN-94-96024) Avail: CASI HC A09/MF A03

The operational mechanism of condenser microphones and some aspects concerning microphone terminology are described. A model of condenser microphones, concerning microphones with a highly tensioned diaphragm as well as microphones with a diaphragm without any initial stress, is presented. Expressions of the mechanical, the electrical, and the total sensitivity are derived. Some practical limitations concerning the influence of temperature changes during operation and the maximum allowable sound pressure are described. An optimization procedure with respect to the sensitivity, which takes into account the maximum allowable sound pressure, is presented. The noise contribution of the microphone preamplifier is considered. Amplifiers, consisting of a MOSFET and a bias resistor or bias diode, and amplifiers, consisting of a JFET and a bias resistor, are analyzed. The integration of a silicon condenser microphone with a PMOS source follower is addressed. Design criteria concerning the integration of the CMOS process and a specific microphone fabrication process are presented. The principle of electromechanical feedback is described. The electrical and mechanical problems and the limitations of feedback are discussed. The feedback was analyzed and tested for two types of actuator signals. The principle of operation of a DC voltage converter as a substitution of a low voltage electret is described. Experimental results of a converter realized in CMOS and the practical operation in combination with a silicon condenser microphone are presented. ESA

N94-31518# Universiteit Twente, Enschede (Netherlands).
A SILICON CONDENSER MICROPHONE: MATERIALS AND TECHNOLOGY Ph.D. Thesis
Patrick Richard Scheeper 1993 204 p Sponsored by Stichting voor Fundamenteel Onderzoek der Materie
(ISBN-9-09-005899-0; ETN-94-96025) Avail: CASI HC A10/MF A03

The development of a condenser microphone in silicon for application in hearing aids is described. The main design criteria are the size (area about 3 by 3 sq mm), the sensitivity (about 10 mV/Pa), and the frequency response (100 to 7 kHz +/-3 dB). A model for the condenser microphone, describing the quasi static as well as the dynamic behavior, is presented. This model is used as a tool to design and optimize microphones. The applicability of Chemical Vapor Deposited (CVD) silicon nitride as a diaphragm material is investigated. The sticking of the diaphragm to the backplate, which is a troublesome phenomenon during the fabrication of the microphones, is investigated. Two different condenser microphone designs are described. It is shown that with one of these designs it is possible to meet the requirements of a hearing aid microphone. A special type of diaphragm that is provided with corrugations, in order to control and improve the mechanical sensitivity of the diaphragm, is addressed. ESA

MODULE GENERATION FOR SELF-TESTING INTEGRATED SYSTEMS Ph.D. Thesis, 21 Jan. 1992
Ronald Pieter vanRiessen 1991 218 p Sponsored by Dutch Program for Innovative Research
(ISBN-9-09-004570-8; ETN-94-96027) Copyright Avail: CASI HC A10/MF A03

Hardware used for self test in VLSI (Very Large Scale Integrated) systems is reviewed, and an architecture to control the test hardware in an integrated system is presented. Because of the increase of test times, the use of self test techniques has become practically and economically viable for VLSI systems. Beside the reduction in test times and costs, self test also provides testing at operational speeds. Therefore, a suitable

combination of scan path and macrospecific (self) tests is required to reduce test times and costs. An expert system that can be used in a silicon compilation environment is presented. The approach requires a minimum of testability knowledge from a system designer. A user friendly interface was described for specifying and modifying testability requirements by a testability expert. A reason directed backtracking mechanism is used to solve selection failures. Both the hierarchical testable architecture and the design for testability expert system are used in a self test compiler. The definition of a self test compiler was given. A self test compiler is a software tool that selects an appropriate test method for every macro in a design. The hardware to control a macro test will be included in the design automatically. As an example, the integration of the self-test compiler in a silicon compilation system PIRAMID was described. The design of a demonstrator circuit by self test compiler is described. This circuit consists of two self testable macros. Control of the self test hardware is carried out via the test access port of the boundary scan standard. ESA

A HIERARCHICAL APPROACH TO TEST GENERATION FOR CMOS VLSI CIRCUITS Ph.D. Thesis
Edward Christiaan Weening 1992 151 p Sponsored by Dutch Program for Innovative Research
(ISBN-9-09-005449-9; ETN-94-96022) Copyright Avail: CASI HC A08/MF A02

A hierarchical approach to the automatic test pattern generation for large digital VLSI circuits, fabricated in CMOS technology, is developed and implemented. The use of information on the circuit's hierarchy, which is readily available from most modern CAD (Computer Aided Design) systems, speeds up the test generation process considerably and enhances the quality of the tests generated. The hierarchical test generation tool can also be integrated in future CAD systems making test generation and testability enhancement during circuit design feasible. The hierarchical approach is described at the switch, functional, and behavioral level. A test pattern generation algorithm at the switch level is presented. Test generation and fault simulation algorithms both using OBDD (Ordered Binary Decision Diagram) functional descriptions of the circuit modules are presented. A test plan generation method at the behavioral level is presented. Practical results show that the hierarchical approach to test generation is more efficient than a conventional, non-hierarchical approach, especially for switch level faults. The results also show that the use of Design For Testability (DFT) circuitry is supported at the behavioral level. ESA

EMPLOYMENT OF A POROUS GOLD ACTUATOR IN ISFET-BASED COULOMETRIC SENSOR-ACTUATOR SYSTEMS WITH APPLICATION TO PROTEIN CHARACTERIZATION Ph.D. Thesis
Jiang Luo 1993 170 p Sponsored by Univ. Twente, and Stichting voor Fundamenteel Onderzoek der Materie
(ISBN-9-09-005887-7; ETN-94-96023) Copyright Avail: CASI HC A08/MF A02

Technological and theoretical aspects of the development and application of ISFET based coulometric sensor-actuator systems are described. An application of such a system to the characterization of proteins is suggested. Diffusion and migration processes at the coulometric sensor-actuator systems with a planar actuator in the application of acid base titration were studied. To minimize the delay time and to limit the diffusion of the species, a porous noble metal actuator is proposed, instead of a planar one, closely covering the gate of the ISFET. The adaptation of the conventional ISFET technology, by which a flat ISFET is proposed and fabricated, is described. An analytical model to describe the developed ISFET based coulometric sensor-actuator systems with gate-covering porous actuator is proposed. A way to operate the developed coulometric sensor-actuator system for a dynamical measurement of the buffer capacity of an analyte is introduced. The buffer capacity as a distinct parameter to characterize proteins was measured. The preliminary results obtained from the measurement of lysozyme and ribonuclease showed different buffer capacities at different pH values. More studies are necessary to further investigate the applicability of this method to characterize proteins. ESA

HIERARCHICAL FAULT CATALOG PROCESS FOR DIAGNOSIS OF ANALOG CIRCUITS Ph.D. Thesis [HIERARCHISCHES FEHLERKATALOGVERFAHREN ZUR DIAGNOSE ANALOGER SCHALTUNGEN]
Albert Hoefel 1993 126 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95730) Avail: Issuing Activity (European Space Agency (ESA))

A practical approach for diagnosis of analog circuits with focus on implementation systems is presented. A fault catalog, which allows a transparent access to the knowledge base, was developed using hierarchical error simulations, assuming a modular structure of the system to be diagnosed. This hierarchical dictionary contains references between the fault cause, some defective circuit components and their interaction, a state at the circuit interface which differs from the nominal behavior and measurable variations of the node voltages inside the circuit. Each fault is classified in a hierarchical structure, regarding its effect on the circuit, the immediate effect at the interface of circuit components and the effect on circuit functionalities. An integration of external knowledge such as accident statistical data from production final controls was made possible. A learning algorithm was added for future correction and enhancement of fault catalog. Object oriented knowledge representation and programming were used for implementing the system. A special expert system shell was implemented for testing the concept, with comfortable system interfaces. Passive systems are shown to be successfully diagnosed, but stability problems appear to be reinforced by fault simulation, because their efficiency strongly depends on individual properties of isolated circuits. APPLICABLE DIMENSIONING AND MEASURE AND TECHNOLOGICAL EXAMINATION OF LONG STATOR-LINEAR MOTORS FOR MAGNETIC HIGH-SPEED RAILWAYS Ph.D. Thesis [ANWENDUNGSNAHE DIMENSIONIERUNG UND MESSTECHNISCHE UEBERPRUEFUNG VON LANGSTATOR-LINEARMOTOREN FUER MAGNETSCHNELLBAHNEN]
Ruediger Fuerst 1993 281 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant BMFT-TV8202/8406)
(ETN-94-95734) Avail: CASI HC A13

Results of measurements aimed at verification of the characteristic magnitudes of long stator/linear motors are presented. Both TRANSRAPID 06 and 07 vehicles were used for tests and the maximal velocity reached 435 km/h. Stator current and voltage, effective power, efficiency, power factor and electromotive force were measured for all dynamic states of the vehicle: acceleration, inertial cruise and braking. The results were discussed in the case of perturbations and incidents of the linear motor, such as electrical short circuits in the long stator winding. Requirements for dimensioning the linear motor were identified and the influence of stator and excitation parameters on the curve electromotive force versus velocity was estimated. ESA

REAL TIME SIMULATION MODEL FOR DESIGNING CONVERTER REGULATION Ph.D. Thesis [ECHTZEIT-SIMULATIONSMODELL FUER DEN ENTWURF VON UMRICHTERSTEUERUNGEN]
Lahcene Benbaouche 1993 189 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95735) Avail: Issuing Activity (European Space Agency (ESA))

A digital real time simulation model for examination of functionality of a network connected converter is achieved following the principle of hybrid computers. The converter and its components such as input filter, pulse inverter, and coupling impedance were simulated and the analog calculation elements and digital control electronics were designed as components. A microcomputer interface was added so that the values of the simulated passive components and the variables of the control system, which is based on pulse width modulation, could be modified. The discretization of the mathematical model and the solution of nonlinear differential equations were represented in state space. Symmetrical and shift controls were compared considering pulse inverter output signal distortion factor. Transfer

functions of the multivariable system and decoupling of active and passive powers were estimated. Object oriented programming of the system was achieved with TURBOPASCAL programming language. ESA

FEASIBILITY STUDY FOR THE RECYCLING OF NICKEL METAL HYDRIDE ELECTRIC VEHICLE BATTERIES
J. C. Sabatini, E. L. Field, I. C. Wu, M. R. Cox, B. M. Barnett, and J. T. Coleman Jan. 1994 99 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000268; NREL/TP-463-6153) Avail: CASI HC A05/MF A02

This feasibility study examined three possible recycling processes for two compositions (AB(sub 2) and AB(sub 5)) of nickel metal hydride electric vehicle batteries to determine possible routes for recovering battery materials. Analysts examined the processes, estimated the costs for capital equipment and operation, and estimated the value of the reclaimed material. They examined the following three processes: (1) a chemical process that leached battery powders using hydrochloric acid, (2) a pyrometallurical process, and (3) a physical separation/chemical process. The economic analysis revealed that the physical separation/chemical process generated the most revenue. DOE

EXAMINATION OF FAST SEMICONDUCTOR DIODES (RECOVERY) WITH RESPECT TO SWITCHING VALVES IN PWM AND RESONANCE DEVICES Ph.D. Thesis [UNTERSUCHUNG VON SCHNELLEN HALBLEITERDIODEN (RECOVERY) IN VERBINDUNG MIT ABSCHALTBAREN VENTILEN IN PWM- UND RESONANZSCHALTUNGEN]
Hagen Gebhardt 1993 152 p In GERMAN Sponsored by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95740) Avail: CASI HC A08

The behavior of fast semiconductor power diodes for applications with high values of di/dt and du/dt is examined. The failure process of the diode was estimated as a function of current transformation velocity and blocking layer temperature with nominal intensity. A specification methodology was introduced from these measurements, which allows the rupture current profile of the examined diode to be predicted for a given application and voltage charge and losses to be evaluated. The conditions of implementation of highly reverse diodes in direct current converters were written and the diode behavior in inductive and capacitive circuits is investigated. The implementation of fast diodes in Pulse Width Modulation (PWM) circuits is examined. SPICE (Simulation Program with Integrated Circuit Emphasis), which provides models of active and passive components for analog circuits in power electronics, is presented. ESA

ANALYSIS AND SYNTHESIS OF MOS TRANSLINEAR CIRCUITS Ph.D. Thesis
Remco John Wiegerink 1992 169 p
(ISBN-9-09-005495-2; ETN-94-96029) Copyright Avail: CASI HC A08/MF A02

Work to generalize and extend the translinear circuit principle to implementation by MOS transistors operating in strong inversion and saturation, is presented. The MOS Translinear (MTL) circuit principle was derived based on the ideal square law transistor characteristic. Both translinear loops containing a single type of transistor and loops containing both n and p type transistors were investigated. In the latter case not all transistor parameters can be dropped from the resulting equation. For loops containing only one type of transistor all transistor parameters cancel and the result is a temperature and process independent relation between the drain current of the transistors. The influence of device imperfections on the MTL principle was analyzed and a systematic analysis method for MTL networks was developed. Two MTL circuit design strategies are proposed: one to implement a desired transfer function by combining the basic functions; and one using the program MTLPLOT as an interactive design tool to approximate a desired transfer function by an MTL loop equation. The designs are illustrated by a four quadrant current multiplier and a nonlinear signal processing function. ESA

AN INVESTIGATION OF A NOVEL MICROSTRIP MAGIC-T
M. W. Katsube Apr. 1992 143 p
(ISBN-0-315-86218-1; CTN-94-61187) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

?he magic T device is commonly found in waveguide form and has unique power division and isolation characteristics which find wide application in the microwave field. The design of such a device in microstrip technology using aperture coupling is investigated. Aperture coupling is a recent method for coupling electromagnetic energy from one substrate layer to another. It has a number of advantages including the separate integration of top and bottom layer circuitry, whereby the ground plane provides the isolation between the respective layers. Results indicate that this working device in microstrip exhibits the required properties of a magic T. Theoretical analysis is pursued to produce ideal circuit models based on modal analysis. A first order approximation is made using the dominant mode, with Lorentz reciprocity and the Poynting theorem. Experimental findings show very good narrow band characteristics with possible broadband operation upon further optimization of the T-branch, which at this stage is the limiting factor. The slot coupling shows good characteristics from about 12 to 18 GHz. The aperture coupled microstrip magic T shows excellent potential in performance for future applications such as integration into microstrip antennas and multilayer processing systems. SIMULATION OF NON-UNIFORM TRANSMISSION LINES FOR WEAKLY DISPERSIVE STRUCTURES M.S. Thesis [SIMULATION DE LIGNES DE TRANSMISSION NON-UNIFORMES POUR DES STRUCTURES PEU DISPERSIVES]
Ricardo Bricout May 1992 180 p In FRENCH
(ISBN-0-315-86525-3; CTN-94-61206) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A study was conducted to obtain the frequency response of microwave

passive circuits containing non-uniform (coupled) transmission lines. By analyzing a general structure in which propagation occurs in an inhomogeneous medium, the performance of common devices like couplers, filters, and matching networks could be improved. The number of discontinuities was kept to a minimum in order to avoid parasitic effects. Most of the work in the study is based on quasi-transverse electromagnetic mode transmission lines, and in order to obtain the desired parameters, it was assumed that a quasi-static analysis is sufficiently accurate. The analysis is based on the spectral domain approach coupled to the method of moments if required by the complexity of the structure. The simulation of the circuit response uses a Chebyshev polynomial decomposition to solve the propagation problem. The results presented include a miniature hybrid microwave integrated circuit interdigital capacitor model, with the measured and simulated response for some test samples. Results are also included for a semi-reentrant mode coupler, soft transitions, and their applications to millimeter wave filters. Double strip suspended substrate lines were used in some circuits. Comparisons were made with measured data if possible and with data obtained with a microwave circuit simulator.

(DE94-006426; PNL-9011) Avail: CASI HC A05/MF A01

This report describes a first phase of effort in providing the Bonneville Power Administration (BPA) with comprehensive tools for model-based analysis of interactions between the Pacific HVDC Intertie (PDCI) and the alternating current (ac) system containing it. The work builds upon the transient stability model coded by Control Technologies, Inc. (CTI) for use in the Electric Power Research Institute (EPRI) Extended Transient-Midterm Stability Package (ETMSP). The general thrust of the effort is that CM's model be interfaced to and tested against all tools provided by EPRI's Power System Analysis Package (PSAPAC) and that these tools be used to investigate options for PDCI use in testing and control of western system dynamics. This will require refinements to the tools, the model, and western system case data. The PSAPAC tool for eigenanalysis is the Small Signal Stability Package (SSSP), useful for performing modal analysis of the multiterminal HVDC (MTDC) system. Such analyses are necessary to design and test an expanded role of the PDCI for power system control. This study focused on testing the application of the MTDC with SSSP. Modifications were made to enable SSSP to read the MTDC model. The PSAPAC and SSSP tools and the MTDC model were evaluated for accuracy and consistency using several modal analysis techniques, including Prony analysis on ETMSP-generated data. Although SSSP appears to be useful in analyzing the PDCI modes, inconsistencies limit the overall usefulness of that approach. The modal frequencies and damping identified by SSSP are inconsistent, indicating SSSP has difficulty analyzing the MTDC representation of the dc systems. The differences between the new and existing models can be used to identify the particular modeling issues associated with SSSP which are presently resulting in inconsistent results.

INFLUENCE OF CARBON DIOXIDE ON ELECTRONIC EQUIPMENT: FIRE EXTINGUISHING WITH LOW CONCENTRATION [KOLDIOXIDS (CO2) PAVERKAN PA ELEKTRONIK: SLAECKNING MEDLAGA KONCENTRATIONER]
M. Arvidson and H. Persson 1993 41 p In SWAHILI Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148749; SP-RAPP-1993:20) Avail: CASI HC A03

Discharge tests and a literature survey have been conducted to investigate the risk for damage on electrical equipment due to low temperatures and electrostatic charges when carbon dioxide (CO2) fire protection systems are operated. The work concentrated on total flooding systems. No indication of adverse effects from CO2 on electrical equipment has been found. Fire tests in a 21.8 cu m room with a computer, electrical cables, or waste paper respectively was performed to investigate the needed CO2 concentration for extinction. At the lowest concentration tested, 26 to 28 volume percent, the fires in the computer and in the cables were extinguished satisfactorily. The fire in the paper reignited when the room was ventilated again.

FINITE ELEMENT ANALYSIS OF TIME-INDEPENDENT SUPERCONDUCTIVITY Ph.D. Thesis
James Joseph Schuler 1993 262 p
Avail: Univ. Microfilms Order No. DA9320476

The focus of the thesis research is the development of electromagnetic (EM) finite elements based upon a generalized four-potential variational principle. The final goal of this research is to formulate, develop, and validate finite element models that can accurately capture electromagnetic, thermal, and material phase changes in a superconductor. The use of the four-potential variational principle allows for downstream coupling of electromagnetic fields with the thermal, mechanical, and quantum effects exhibited by superconducting materials. The use of variational methods to model an electromagnetic system allows for a greater range of applications than just the superconducting problem. In fact, the four-potential variational principle can be used to solve a broader range of EM problems than any of the currently available formulations. It also reduces the number of independent variables from six to four while easily dealing with conductor/insulator interfaces. This methodology has been applied to a range of EM field problems. Seven problems are presented here. These applications show the power of the four-potential variational method, when augmented by Lagrange multiplier weighted constraint equations, to solve diverse EM field problems. All of the finite element models predict EM quantities exceptionally well and match the expected physical behavior. The results obtained with these finite element models display in previously unseen detail the physics of the superconducting charge carriers within the boundary layer of a Ginzburg-Landau superconductor. These results are compared to the physics of a low viscosity fluid problem. From this analogy, a physical argument is advanced about superconductors. This argument is that the small resistance that exists within a superconductor is similar in origin to the viscous effects of fluids and can be attributed to collisions that occur between moving and static charge carriers.

Hydrogen Peroxide has been shown to be efficiently electro-reduced at an electrode modified with a hydrophilic, permeable film of horseradish peroxidase covalently bound to a 3-dimensional epoxy network having polyvinyl pyridine (PVP)-complexed Os(bpy)2C1+2/+3 redox centers. Four peroxide sensing cathodes based on peroxidases from Arthromyces ramosus, horseradish and bovine milk are compared. Their sensitivity at O.OV (SCE) ranges from 0.1 - 1.0 A sq cm/M, and their limiting currents relate to the enzyme's ability to complex with the redox epoxy network. DTIC

Three new failure analysis techniques for integrated circuits (IC's) were developed using localized photon probing with a scanning optical microscope (SOM). The first two are light-induced voltage alteration (LIVA) imaging techniques that do the following: (1) localize open-circuited and damaged junctions; and (2) image transistor logic states. The third technique uses the SOM to control logic states optically from the IC backside. LIVA images are produced by monitoring the voltage fluctuations of a constant current power supply as a laser beam is scanned over the IC. High selectivity for localizing defects was demonstrated using the LIVA approach. Logic state mapping results, similar to previous work using biased optical beam induced current (OBIC) and laser probing approaches were also produced using LIVA. Application of the two LIVA based techniques to backside failure analysis was demonstrated using an infrared laser source. Optical logic state control is based upon earlier work examining transistor response to photon injection. The physics of each method and their applications for failure analysis are described. DOE

PROMISING FUTURE ENERGY STORAGE SYSTEMS: NANOMATERIAL BASED SYSTEMS, Zn-AIR, AND ELECTROMECHANICAL BATTERIES
R. Koopman and J. Richardson Oct. 1993 8 p Presented at the Workshop on Advanced Components for Electric and Hybrid Electric Vehicles, Gaithersburg, MD, 27-28 Oct. 1993
(Contract W-7405-eng-48)
(DE94-007443; UCRL-JC-115382; CONF-9310282-2) Avail: CASI HC A02/MF A01

Future energy storage systems will require longer shelf life, higher duty cycles, higher efficiency, higher energy and power densities, and be fabricated in an environmentally conscious process. This paper describes several possible future systems which have the potential of providing stored energy for future electric and hybrid vehicles. Three of the systems have their origin in the control of material structure at the molecular level and the subsequent nanoengineering into useful device and components: aerocapacitors, nanostructure multilayer capacitors, and the lithium ion battery. The zinc-air battery is a high energy density battery which can provide vehicles with long range (400 km in autos) and be rapidly refueled with a slurry of zinc particles and electrolyte. The electromechanical battery is a battery-sized module containing a high-speed rotor integrated with an iron-less generator mounted on magnetic bearings and housed in an evacuated chamber. DOE

DESIGN OF A HIGH POWER X-BAND MAGNICON AMPLIFIER
S. H. Gold, O. A. Nezhevenko, V. P. Yakovlev, and B. Hafizi 14 Feb. 1994 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277001; NRL/MR/6790-94-7408) Avail: CASI HC A03

We present a design study for an X-band frequency-doubling magnicon amplifier driven by a 500 keV, 172 A beam from a field emission diode. This study makes use of steady state particle simulations employing the realistic fields of magnicon cavities connected by beam tunnels and includes the effects of finite electron beam diameter. The simulations propagate an electron beam through a sequence of deflection cavities at 5.7 GHz, followed by an output cavity that operates at 11.4 GHz. The deflection cavities and the output cavity contain synchronously rotating TM modes. The deflection cavities progressively spin up the beam transverse momentum, until alpha defined equal to v(sub perpendicular)/v(sub z) is greater than or equal to 1, where v(sub perpendicular) and v(sub z) are the velocity components perpendicular and parallel to the axial magnetic field. The output cavity uses this synchronously gyrating beam to generate microwave radiation at twice the drive frequency. Self consistency of the simulation is achieved by iteration until power balance exists in each cavity and until the optimum RF phase in each cavity is determined. The final magnicon circuit should produce 20 to 50 MW at 11.4 GHz, depending on initial beam diameter, with a drive power of 1kW at 5.7 GHz. DTIC

We have succeeded in transferring the high growth rate diamond process from our 8 kW prototype to our 75 kW reactor. Additionally, we generated the first free-standing diamond films of greater than 4 in. x 4 in. size. Our efforts have concentrated on the following: improving the growth rate and film quality of the diamond growth process, exploring the operating envelope of the 75 kW reactor, and designing improvements to fully realize the potential of the large scale high growth system. New program components have been initiated for developing release techniques on large substrates, improving film flatness, and improving uniformity of thickness and morphology. A thermal conductivity, test stand is in the planning stages for in-house testing of samples in the near future. DTIC

WORKSHOP ON COMMERCIALIZATION OF PULSED POWER SCIENCE AND TECHNOLOGY PROCEEDINGS
20 Aug. 1993 147 p Workshop held in San Francisco, CA, 18-20 Aug. 1993
(AD-A276987) Avail: CASI HC A07/MF A02

The new international environment has opened opportunities for pulsed power research that were not possible a few years ago. Pulsed power technology developed with Department of Defense support was primarily directed towards Department of Defense goals -- perhaps more so than other areas of critical technology. There are, however, many significant applications for pulsed power in the commercial sector. The ability to tailor power pulse shapes and sequences and efficiently deliver energy in a pulsed, rather than DC or traditional AC mode, opens new horizons for commercial applications of lasers and accelerators, in medicine and pollution control, advanced motor control, and many other areas. There will be many applications for efficient, long-lived, reliable pulsed power that can be matched to applications requiring specialized voltage and current. The 1993 Workshop on Commercialization of Pulsed Power Science and Technology brought together experts in the full range of problems facing technology transfer to discuss the issues facing commercialization and marketing. Those involved represented in addition to pulsed power expertise, experience in licensing, development, product engineering and marketing of new technology. The Workshop Proceedings provides a summary of discussion and expertise in all these areas. DTIC

This work has concentrated on basic technologies for the fabrication of devices which can be used in optical interconnect and optical computing applications. One of the most important issues is the technology for integration of different devices on the same substrate. Three different possibilities were investigated: heteroepitaxial growth, epitaxial lift-off and patterned epitaxy. The heteroepitaxial technique and the epitaxial lift-off can be used to integrate optoelectronic and electronic devices on the same substrate (resulting in optoelectronic integrated circuits or OEIC's). In terms of device performance and material quality, very good results were obtained with the epitaxial lift-off. This was reflected in the realization of a number of interesting devices and optoelectronic integrated circuits. The heteroepitaxial growth still suffers from the large defect density and although clear improvements were obtained, no good device results could be obtained. As an alternative the bonding by atomic rearrangement was also successfully investigated. The patterned growth technique has a different application field and has important advantages in the fabrication of photonic integrated circuits (PIC) where two (or more) optoelectronic devices are integrated and coupled optically (e.g. laser and waveguide). Sony lithium-ion cells type 20500 were tested and evaluated at different temperatures, discharge rates from C/2 to 3C, and with different charge voltage cutoffs. The capacity was typical 0.8 Ah at the C/2 rate at 25 C when charged to 4.1-volt cutoff. An energy density of 70 Wh/kg and 400 or more cycles was demonstrated. Charging to 4.25 volts and higher cutoffs was tested without a safety problem. The Sony charger provided a constant potential charge at 8.2 volts (4.1 volts/cell). It replaces 90% of capacity within one hour and it shut off the charging after 2-1/2 hours. DTIC

Substantial increases in the cost effectiveness and range of naval underwater vehicles are possible by virtue of advances made, in this program, to silver-zinc, vehicle propulsion batteries. To improve battery cycle life and energy density, electropermeable membranes (EPM's) were used as additives and/or as coatings for the negative electrodes and as coatings for conventional separator materials. Also, bismuth oxide was tested as an additive to the negative electrodes and P2291-40/20, a radiation-grafted polyethylene film, as a separator used in conjunction with silver-treated cellophane. EPM's used as negative electrode additives and also as coatings for Celgard 2500 microporous polypropylene greatly improved cells. Cells with EPM's used as coatings for the negative electrodes failed rapidly because of an error in formulation. Cells with 10 percent bismuth oxide in the negative electrodes exhibited substantially lower capacity than the standard cells and were removed from the test. Cells with radiation-grafted polyethylene separators provided fewer cycles than the standard cells, with 5 percent higher capacity and 6 percent lower utilization of active materials by cycle 60. However, the slightly better capacity of these cells, realized due to the additional space available for active materials, does not compensate for their generally unimpressive performance. DTIC

N94-32336 Naval Postgraduate School, Monterey, CA.
OPTIMAL ADAPTIVE ESTIMATION ALGORITHM FOR HARMONIC CURRENT REDUCTION USING POWER LIMITED ACTIVE LINE CONDITIONERS M.S. Thesis
Joel E. Zupfer Dec. 1993 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277354) Avail: CASI HC A04

The ability to measure and compensate for power line harmonics has become a growing area of interest because of today's commonly used electronic equipment. Since the number and relative magnitudes of the harmonics on the power line are a function of the load, estimation of an equivalent load can be accomplished. Because of variation in the load, the need for an adaptive algorithm is imperative. Thus far, few algorithms for determining harmonic contents have not dealt with the problem associated with the limited power of the line conditioner. This thesis deals with a previously known harmonic compensating algorithm and introduces a new algorithm which both compensates for harmonic noise and estimates the load as a transformation matrix depending on the associated transfer function of the active line conditioner in use. FROM DISPLAY AND PWB TO MCMs: LARGE PANEL MANUFACTURING
D. W. Palmer and W. Worobey 1994 10 p Presented at the International Society for Hybrid Multichip Modules, Denver, CO, 13-15 Apr. 1994
(Contract DE-AC04-94AL-85000)
(DE94-007855; SAND-94-0009C; CONF-9404118-1) Avail: CASI HC A02/MF A01

Considerable manufacturing development is currently aimed at reducing high density Multichip Module (MCM) cost through the use of large panels (greater than 40 cm x 40 cm) to fabricate many interconnection substrates in parallel. This drive for low cost MCM manufacturing is aided by the growing base of similar panel technology for the Printed Wiring Board (PWB) and Flat Panel display industries. It is toward this experience that

the infant large panel MCM efforts are looking. In particular, the MCM Consortium formed by the Electronic Industry Association (EIA) and funded under the federal TRP effort is charged with developing a line of equipment optimized for large panel, fine line manufacture. PWB line definition research into large panels of glass and smooth non-woven laminate at 2-4 mil lines and spaces reveals that present equipment and processes are extendible well beyond commercial PWB product. In contrast, the ultra-cleanliness and spin coating of the silicon integrated circuit technology prove too expensive when scaled from 150mm diameter wafers to 560mm panels. Thus low waste photoresist (and other polymer dielectrics) application methods are needed for large panel manufacture. Similarly, PWB contact photomasking is nearing limits at 2-4 mil feature size, and projection or maskless direct write processes may be needed. Even small hand-held flat panel displays are manufactured from large panels to reduce the cost per display for conductive and dielectric layer deposition and patterning. In addition, as low cost flat displays become larger and improve in resolution, the line pitch and density approach that needed in high density MCM's. DOE

ARCING IN SPACE STRUCTURES IN LOW EARTH ORBIT Final Report, 1 Jan. 1990 - 29 Dec. 1991
B. L. Upschulte, W. J. Marinelli, G. Weyl, and K. L. Carleton Jan. 1992 127 p
(Contract NAS3-25797; SBIR-10.01-9030)
(NASA-CR-194223; NAS 1.26:194223; PSI-2123/TR-1153) Avail: CASI HC A07/MF A02

This report describes results of an experimental and theoretical program to investigate arcing of structures containing dielectric and conducting materials when they are biased negatively with respect to a plasma. An argon ion source generated Ar(+) ions of directed energy 20 to 40 eV and density approximately 10(exp 7) cm(exp -3) that impinged upon samples containing a dielectric material on top of a negatively biased Kovar plate. Arcing events were studied for bias voltages between -300 and -1000V with respect to the ion beam. The samples were Dow Corning 93-500 adhesive on Kovar, fused silica cover slips bonded on Kovar, and silicon solar cells mounted on Kovar. Measurements of discharge current, Kovar plate voltage, and radiation from the arc versus time were carried out. Microsecond duration exposure images and optical spectra in the 0.24 to 0.40 micron band were also acquired during arcing events. Arcing events were found to be associated with exposed adhesive and means were found to eliminate arcing altogether. The charging of a silica cover plate and the fields around the plate were calculated using a particle-in-cell code. Models were developed to explain the ignition of the arc and the physical processes occurring during the discharge. Author

RADIATION TOLERANT, HIGH SPEED, LOW POWER, GALLIUM ARSENIDE LOGIC M.S. Thesis
Kurt A. Wolfe Dec. 1993 116 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277293) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Gallium arsenide (GaAs) circuits are largely immune to slowly accumulated radiation doses and therefore do not need the shielding required by complementary metal oxide semiconductor (CMOS) devices. This attribute renders GaAs circuits particularly attractive for spacecraft and military applications. However, it has been shown that GaAs circuits with short gate length transistors are excessively susceptible to single event upsets (SEU) due to enhanced charge collection at the edges of the gate called 'edge effect.' This thesis studies the SEU problem in two parts. Extensive computer modeling and simulation of a charged particle passing through various transistors of a low power, two-phase dynamic MESFET logic (TDFL) test chip was conducted using HSPICE in the first part. In the second part, new GaAs logic topologies are developed, simulated, and layed out in integrated circuits which require less power than directly coupled MESFET logic (DCFL) and should be less susceptible to single event upsets than TDFL circuits. ENERGY STORAGE SPECIFICATION REQUIREMENTS FOR HYBRID-ELECTRIC VEHICLE
A. F. Burke Sep. 1993 36 p
(Contract DE-AC07-76ID-01570)
(DE94-008642; EGG-EP-10949) Avail: CASI HC A03/MF A01

A study has been made of energy storage unit requirements for hybrid-electric vehicles. The drivelines for these vehicles included both primary energy storage units and/or pulse power units. The primary energy storage units were sized to provide 'primary energy' ranges up to 60 km. The total power capability of the drivelines were such that the vehicles had 0 to 100 km/h acceleration times of 10 to 12 s. The power density requirements for primary energy storage devices to be used in hybrid vehicles are much higher than that for devices to be used in electric vehicles. The energy density and power density requirements for pulse-power devices for hybrid vehicles, are not much different than those in an electric vehicle. The cycle life requirements for primary energy-storage units for hybrid vehicles are about double that for electric vehicles, because of the reduced size of the storage units in the hybrid vehicles. The cycle life for pulse-power devices for hybrid vehicles is about the same as for electric vehicles having battery load leveling. Because of the need for additional components in the hybrid driveline, the cost of the energy storage units in hybrid vehicles should be much less (at least a factor of two) than those in electric vehicles. There are no presently available energy storage units that meet all the specifications for hybrid vehicle applications, but ultracapacitors and bipolar lead-acid batteries are under development that have the potential for meeting them. If flywheel systems having a mechanical system energy density of 40 to 50 W(center dot)h/kg and an electrical system power density of 2 to 3 kw/kg can be developed, they would have the potential of meeting specifications for primary storage and pulse power units. NEW THICK FILM FEEDTHROUGH CONFIGURATIONS
C. T. Fritsche Mar. 1994 8 p
(Contract DE-AC04-76DP-00613)
(DE94-008706; KCP-613-5330) Avail: CASI HC A02/MF A01

An investigation determined that thick film feedthroughs could successfully be printed with 12-mil holes in 20-mil square pads, 10-mil holes in 15-mil square pads, 6 x 12-mil oval-shaped holes in 10 x 35-mil rectangular pads, and 6 x 9-mil oval-shaped holes in 10 x 25-mil rectangular pads. The results were verified by printing test vehicles containing the four feedthrough configurations, electrically testing the feedthroughs for continuity, and cross-sectioning each of the feedthroughs in two axes. CONDUCTIVITY MEASUREMENTS OF CERIA-BASED SOLID ELECTROLYTES USING AC IMPEDANCE
G. B. Balazs and R. S. Glass Feb. 1994 15 p Presented at the 185th Electrochemical Society Meeting, San Francisco, CA, 22-27 May 1994
(Contract W-7405-eng-48)
(DE94-007380; UCRL-JC-116378; CONF-940529-1) Avail: CASI HC A03/MF A01

The ionic conductivities of cerium oxide samples doped separately with oxides of the entire lanthanide series (except promethium) and yttrium were measured using AC impedance. A wide variation in conductivities was observed, from 1 x 10(exp -2) S/cm for Ce(0.8)Sm(0.2)O(1.9) to 2 x 10(exp -4) S/cm for undoped ceria at 600 C. Many of these ceria systems exhibited ionic conductivities higher than those of zirconia systems, making ceria a logical choice for certain low temperature applications. A correlation was found between the ionic radii of the dopant and the corresponding ionic conductivities, with ceria doped with Gd2O3, Sm2O3, and Y2O3 exhibiting the highest values. In addition, the relative contributions of the grain boundaries and grain interiors to the overall resistance was measured. The ceria/samaria and ceria/gadolinia systems showed a different response than the ceria/yttria system with regard to the effect of sintering time on the relative contributions. DOE

PROCEEDINGS OF THE AD HOC WORKSHOP ON CERAMICS FOR LI/FeS2 BATTERIES
1993 240 p Workshop held in Oak Brook, IL, 29-30 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-31-109-eng-38)
(DE94-007460; ANL/CMT/Proc-81920; CONF-9309203) Avail: CASI HC A11

Representatives from industry, the U.S. Advanced Battery Consortium (USABC), DOE, national laboratories, and other government agencies met to develop recommendations and actions for accelerating the development of ceramic components critical to the successful introduction of the Li/FeS2 bipolar battery for electric vehicles. Most of the workshop is devoted to electrode materials, bipolar designs, separators, and bipolar plates. The bulk of this document is viewgraphs and is divided into: ceramics, USABC overview, SAFT's Li/FeS2 USABC program, bipolar Li/FeS2 component development, design requirements for bipolar plates, separator design requirements, compatibility of ceramic insulators with lithium, characterization of MgO for use in separators, resistivity measurements of separators, sintered AlN separators for LiMS batteries, etc. DOE

THIN-FILM DECOUPLING CAPACITORS FOR MULTI-CHIP MODULES
D. Dimos, S. J. Lockwood, R. W. Schwartz, and M. S. Rogers 1994 6 p Presented at the 44th Electronic Components and Technology Conference, Washington, DC, 1-4 May 1994
(Contract DE-AC04-94AL-85000)
(DE94-007743; SAND-94-0163C; CONF-940596-2) Avail: CASI HC A02/MF A01

Thin-film decoupling capacitors based on ferroelectric lead lanthanum zirconate titanate (PLZT) films are being developed for use in advanced packages, such as multi-chip modules. These thin-film decoupling capacitors are intended to replace multi-layer ceramic capacitors for certain applications, since they can be more fully integrated into the packaging architecture. The increased integration that can be achieved should lead to decreased package volume and improved high-speed performance, due to a decrease in interconnect inductance. PLZT films are fabricated by spin coating using metal carboxylate/alkoxide solutions. These films exhibit very high dielectric constants ((var epsilon) greater than or equal to 900), low dielectric losses (tan(delta) = 0.01), excellent insulation resistances (rho greater than 10(exp 13) (Omega)-cm at 125 C), and good breakdown field strengths (E(sub B) = 900 kV/cm). For integrated circuit applications, the PLZT dielectric is less than 1 micron thick, which results in a large capacitance/area (8-9 nF/sq mm). The thin-film geometry and processing conditions also make these capacitors suitable for direct incorporation onto integrated circuits and for packages that require embedded components. DOE

N94-32662 Los Alamos National Lab., NM.
PARTICLE-IN-CELL (PIC) CODE SIMULATION RESULTS AND COMPARISON WITH THEORY SCALING LAWS FOR PHOTOELECTRON-GENERATED RADIATION
T. M. Dipp Dec. 1993 80 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-006132; LA-12628-MS) Avail: Issuing Activity (Department of Energy (DOE))

The generation of radiation via photoelectrons induced off of a conducting surface was explored using Particle-In-Cell (PIC) code computer simulations. Using the MAGIC PIC code, the simulations were performed in one dimension to handle the diverse scale lengths of the particles and fields in the problem. The simulations involved monoenergetic, nonrelativistic photoelectrons emitted normal to the illuminated conducting surface. A sinusoidal, 100% modulated, 6.3263 ns pulse train, as well as unmodulated emission, were used to explore the behavior of the particles, fields, and generated radiation. A special postprocessor was written to convert the PIC code simulated electron sheath into far-field radiation parameters by means of rigorous retarded time calculations. The results of the small-spot PIC simulations were used to generate various graphs showing resonance and nonresonance radiation quantities such as radiated lobe patterns, frequency, and power. A database of PIC simulation results was created and, using a nonlinear curve-fitting program, compared with theoretical scaling laws. Overall, the small-spot behavior predicted by the theoretical scaling laws was generally observed in the PIC simulation data, providing confidence in both the theoretical scaling laws and the PIC simulations. DOE

THE RELATIVE PERFORMANCE OF FeS2 AND CoS IN LONG-LIFE THERMAL-BATTERY APPLICATIONS
R. A. Guidotti and F. W. Reinhardt 1994 8 p Presented at the 185th Electrochemical Society Meeting, San Francisco, CA, 22-27 May 1994
(Contract DE-AC04-94AL-85000)
(DE94-006145; SAND-93-3865C; CONF-940529-2) Avail: CASI HC A02/MF A01

The relative performance of FeS2 and CoS2 was measured in single cells based on the LiBr-KBr-LiF 0 eutectic electrolyte over a temperature range of 400 to 550 C using both standard (dry) and flooded anodes. This electrolyte is designed to be used in long-life thermal-battery applications because it has a lower melting point (313 C) and a higher electrical conductivity than the standard LiCl-KCl eutectic (m.p.= 352 C). The cells were continuously pulsed for 1 ms every 10 ms from a background current density of 190 mA/sq cm to 1,130 mA/sq cm until end of life. DOE

AUTOMATED FIBER PIGTAILING TECHNOLOGY
O. T. Strand, M. E. Lowry, S. Y. Lu, D. C. Nelson, D. J. Nikkel, M. D. Pocha, and K. D. Young Feb. 1994 6 p Presented at the 44th Electronic Components and Technology Conference, Washington, DC, 1-4 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-007072; UCRL-JC-116148; CONF-940596-1) Avail: CASI HC A02

The high cost of optoelectronic (OE) devices is due mainly to the labor-intensive packaging process. Manually pigtailing such devices as single-mode laser diodes and modulators is very time consuming with poor quality control. The Photonics Program and the Engineering Research Division at LLNL are addressing several issues associated with automatically packaging OE devices. A furry automated system must include high-precision fiber alignment, fiber attachment techniques, in-situ quality control, and parts handling and feeding. This paper will present on-going work at LLNL in the areas of automated fiber alignment and fiber attachment. For the fiber alignment, we are building an automated fiber pigtailing machine (AFPM) which combines computer vision and object recognition algorithms with active feedback to perform sub-micron alignments of single-mode fibers to modulators and laser diodes. We expect to perform sub-micron alignments in less than five minutes with this technology. For fiber attachment, we are building various geometries of silicon microbenches which include on-board heaters to solder metal-coated fibers and other components in place; these designs are completely compatible with an automated process of OE packaging. We have manually attached a laser diode, a thermistor, and a thermo-electric heater to one of our microbenches in less than 15 minutes using the on-board heaters for solder reflow; an automated process could perform this same exercise in only a few minutes. Automated packaging techniques such as these will help lower the costs of OE devices. DOE

The measurement of layer-to-layer feature overlay will, in the foreseeable future, continue to be a critical metrological requirement for the semiconductor industry. Meeting the image placement metrology demands of accuracy, precision, and measurement speed favors the use of electrical test structures. In this paper, a two-dimensional, modified voltage-dividing potentiometer is applied to a short-loop VLSI process to measure image placement. The contributions of feature placement on the reticle and overlay on the wafer to the overall measurement are analyzed and separated. Additional sources of uncertainty are identified, and methods developed to monitor and reduce them are described. DOE

OXIDATION RESISTANT COPPER Patent Application

Alan S. Edelstein, inventor (to Navy), Forrest H. Kaatz, inventor (to Navy), and Vincent G. Harris, inventor (to Navy) 15 Nov. 1993 22 p

(AD-D016099; US-Patent-Appl-SN-151693) Avail: CASI HC A03/MF A01

Oxidation resistant particles composed of copper and at least one metal having a valence of +2 or +3 and having an intermediate lattice energy for the metal in its hydroxide form are presented. The metal is selected from nickel, cobalt, iron, manganese, cadmium, zinc, tin, magnesium, calcium and chromium. In one embodiment, the phases of copper and at least one metal in the particles are separate and the concentration of the metal is greater near the surface of the particles than inwardly thereof. Process for making the oxidation resistant copper particles includes the steps of dissolving a copper salt and a salt of at least one of the metals in a suitable solvent or diluent; forming primary particles of copper and at least one metal in basic form by mixing a base and the salt solution; separating, washing and drying the primary particles; reducing the primary particles to metallic form; and heat treating the particles in metallic form at an elevated temperature. AN ELECTRICAL TEST SYSTEM FOR CONDUCTOR FORMATION PROCESS ANALYSIS

T. A. Estes and R. J. Rhodes 1994 7 p Presented at the Institute for Interconnecting and Packaging Electronic Printed Circuits Spring Expo, Boston, MA, 24-27 Apr. 1994

(Contract DE-AC04-94AL-85000)

(DE94-007291; SAND-94-0597C; CONF-9404112-1) Avail: CASI HC A02/MF A01

Sandia National Laboratories has designed and built an electrical test system which fulfills a requirement to quickly, accurately, and precisely measure the resistance of conductors formed on Printed Wiring Board (PWB) substrates. This requirement stems from the need to measure small variations in conductors and thus to determine the source of the variations. With this test technology, experiments can be conducted with new materials, equipment, and processes in a timely and scientific manner. Conductor formation processes can be optimized for both conductor yield and uniformity, and process equipment can be fine-tuned prior to processing product to ensure that conductor attributes fulfill requirements. Significant resources were spent by Sandia National Laboratories and Texas Instruments modifying commercially available two-probe testers. AT&T has built a two-probe tester and obtained a commercially available 'bed-of-nails' test system. The two-probe systems have limitations in speed and precision; the 'bed-of-nails' system has proved to be superior to the two-probe designs but is expensive and lacks test pattern flexibility and ease of use. Due to the need to establish a testing technology which meets the requirements of Sandia National Laboratories and the National Center for Manufacturing Sciences PWB Consortium Imaging Team (current Imaging Team members; AT&T, Texas Instruments, AlliedSignal, IBM, and Sandia National Laboratories), a prototype test system was designed and built by Sandia. This paper will discuss the design and performance of the test system and the results of a comparison to other test systems. DOE

EDD-7 ELECTRIC CHARGE POINT METER TEST RESULTS

C. R. Mersman Sep. 1993 71 p

(Contract DE-AC07-76ID-01570)

(DE94-008515; EGG-EP-10999) Avail: CASI HC A04/MF A01

The results of tests evaluating the electric switching portion of the EDD-7 Electric Charge Point Meter (ECPM) are presented. The ECPM is a modified parking meter that allows the purchase of 120 or 240 volt electric power. The ECPM is designed to make electricity available at any vehicle parking location. The test results indicate that the ECPM operated without failure through a series of over current and ground fault tests at three different test temperatures. The magnitude of current required to trip the over current protection circuitry varied with temperature while the performance of the ground fault interruption circuitry did not change significantly with the test temperature. DEVELOPMENT OF NICKEL AND METAL HYDRIDE SECONDARY BATTERY
T. Ikeya, K. Kumai, and T. Iwahori May 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-757270; CRIE-T-92089) Avail: CASI HC A03

This paper describes contrivances on a nickel/metal hydride secondary battery using a hydrogen absorbing alloy modified by mechanical processing, and reports the battery characteristics. The test electrode (cathode) was made from a hydrogen absorbing alloy powder which has been mixed with cobalt powder at 20%, mechanically processed in a rotating ball mill, rolled into sheets, and sandwiched with nickel mesh sheets. The counter electrode is a sintered nickel electrode, the electrolyte uses potassium hydroxide aqueous solution, and the separators are made of polypropylene non-woven fabric. The result of battery characteristic tests using the test electrodes indicated that the battery has longer life than conventional batteries. A nickel electrode capacity regulated battery having the same configuration as practically used batteries exhibited no capacity decrease even after 1000 charge/discharge cycles. The main factor for this was thought that metals added by the mechanical processing are bonded locally on the alloy surface forming electrically conductive microstructure accompanying dissolving and depositing reactions to produce cobalt alloy that shows catalytic activity on the alloy surface. (AD-A277617) Avail: CASI HC A01/MF A01

During the past quarter we have made considerable progress on the design and layout of the five-processor ring IC, although we missed the deadline for the Jan. 1994 MOSIS 0.8 micron CMOS fabrication run. The next available run has an Apr. 6 deadline, and we hope to have our chip on the run, or at the worst on the following one. We are trying to be as cautious as possible in our fabrication of this rather expensive chip in order to maximize our chances that only one fabrication run will be necessary. As we have mentioned previously, the chip will be a drop in replacement for our one-processor chip, which was found fully functional on its first fabrication, and which was described in our previous progress report. We have also made good progress on our IBM PC boards. DTIC

The present invention relates to a grounding ring which may be used in ground adapters. The grounding ring has a structure resembling a miniature box girder with an irregular hexagonal cross section and is bent into a toroidal configuration. The grounding ring is characterized by increased wall areas for establishing electrical contact between a surface of a conductor and a surface of a stuffing tube, grounding conduit, or shield grounding fitting. The grounding ring provides improved EM performance and better capacitive coupling. DTIC

(Grant NAG3-1139)
(NASA-CR-195240; NAS 1.26:195240; ASU-DWA-0080) Avail: CASI HC A03/MF A01

This report explains the Advanced Partial Discharge Measuring System in ASU's High Voltage Laboratory and presents some of the results obtained using the setup. While in operation an insulation is subjected to wide ranging temperature and voltage stresses. Hence, it is necessary to study the effect of temperature on the behavior of partial discharges in an insulation. The setup described in this report can be used to test samples at temperatures ranging from -50 C to 200 C. The aim of conducting the tests described herein is to be able to predict the behavior of an insulation under different operating conditions in addition to being able to predict the possibility of failure. This paper presents the development of III-V based pseudomorphic high electron mobility transistors (PHEMT's) designed to operate over the temperature range 77 to 473 K (-196 to 200 C). These devices have a pseudomorphic undoped InGaAs channel that is sandwiched between an AlGaAs spacer and a buffer layer; gate widths of 200, 400, 1600, and 3200 micrometers; and a gate length of 2 micrometers. Measurements were performed at both room temperature and 473 K (200 C) and show that the drain current decreases by 30 percent and the gate current increases to about 9 microns A (at a reverse bias of -1.5 V) at the higher

temperature. These devices have a maximum DC power dissipation of about 4.5 W and a breakdown voltage of about 16 V. Author (revised)

(AD-A278039) Avail: CASI HC A06

MICROX is a silicon-on-insulator (SOI) technology using high resistivity (greater than 3,000 ohm-cm) silicon substrates to integrate RF and digital circuits. Channel length (down to 1/4 micrometers) and gate arrangement influences on frequency, power, and noise performance of FET's were characterized. Processing steps for MICROX MMIC's (Miniature Microwave Integrated Circuits) were identified and developed. The best MICROX power result was 250 mW per mm of gate periphery (8.45 dB of associated gain, 49% Power Added Efficiency (PAE)) at 2 GHz from a non-LDD device (gate length of 0.55 micrometers). At 10 GHz an LDD FET (gate length, 1/4 Am) delivered 60 mW/mm of power (PAE, 19%; gain, 4.6 dB). The best broadband noise figure (non-LDD FET; gate length, 0.48 micrometer) was 0.8 dB with 17.7 dB of associated gain at 2 GHz. These results are superior to those reported for alternative types of high frequency silicon FETS. Demonstration circuits (several L/S band amplifiers, a multi-bit attenuator, and a FET mixer) were selected, designed, simulated, and implemented in MICROX. MICROX provides higher frequency capability than alternative silicon approaches by eliminating parasitic capacitances associated with low resistivity bulk silicon. With silicon IC fabrication methods, MICROX offers a reduced risk route to high volume, low cost manufacturing of RF and high speed digital IC's, compared to GaAs. DTIC

The Pulsed Power and Plasma Science Laboratory at the University of New Mexico (UNM) has completed its initial phase of research on repetitively pulsed high power backward-wave oscillators (BWO's). The aggressive program that we had established seeked to address three basic goals: (1) understand the physics of high efficiency vacuum BWO's using the Sinus-6 repetitively pulsed electron beam accelerator, (2) study vacuum and initiate plasma-filled long pulse BWO operations using the modified PI-110A accelerator, and (3) study the prospects of incorporating ferroelectric ceramic cathodes in high power electron beam-driven microwave sources to improve their operations in the long pulse regime. The temperature dependence of single-event burnout (SEB) in n-channel power metal-oxide-semiconductor field effect transistors (MOSFET's) is investigated experimentally and analytically. Experimental data are presented which indicate that the SEB susceptibility of the power MOSFET decreases with increasing temperature. A previously reported analytical model that describes the SEB mechanism is updated to include temperature variations. This model is shown to agree with the experimental trends. DTIC

(Contract DAAL03-92-G-0257)
(AD-A278014) Avail: CASI HC A03/MF A01

There exists a critical need for efficient local oscillators for heterodyne mixers operating in the 300 to 3000 GHz region. Applications include space-based submillimeter wave imaging arrays, airborne atmosphere spectroscopy, all-weather imaging radar, non-destructive testing, plasma diagnostics, weapon and contraband detection, and communications. In order to address these problems, we propose a novel low power semiconductor device which uses time delays from a common optical

pulse train to achieve a much higher frequency electrical pulse train, which contains a strong component and appreciable power of the desired submillimeter-wave harmonic for the output and which can be readily coupled electrically or radiatively to a receiver. In our effort, we developed a concept of linear array of ten optical switches. The microwave output from the switches can be in the 100 - 200 GHz frequency range. In order to implement this concept, a single photo-conductive switch of polycrystalline InGaAs was fabricated and tested. DTIC

THE SMALL-SCALE TOPOLOGY OF A 2:1 ASPECT-RATIO ELLIPTIC JET Ph.D. Thesis
Thomas Robert Austin 1993
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

The topology of the large-scale vortices and associated small-scale structures that together constitute the free shear layer of a subsonic 2:1 aspect-ratio elliptic jet is investigated by phase-averaged analyses of turbulent velocity signals. The range of Reynolds numbers is extended in this investigation from 4 x 10(exp 4) to 1.7 x 10(exp 5) based on nozzle hydraulic diameter and corresponds to exit velocities from 20 to 85 m/s. Axisymmetric forcing at the preferred mode frequency at St = 0.42 is performed to induce a collective interaction among the initial vortices to form coherent structures at the preferred mode frequency near the nozzle. Successive vortex mergings are effectively suppressed such that the evolution of the turbulent flow from the nozzle to the end of the potential core is driven solely by azimuthally deforming, self-inducting vortices. The effects of vortex self-induction on the large-scale entrainment and the small-scale production processes, respectively, can be isolated from vortex merging effects. An initial azimuthally varying distribution of vorticity is created in the boundary layer at the jet exit. The degree of asymmetry of the initial boundary layer thickness is dictated by the nozzle geometry, Reynolds number, temperature and frequency content. The self-induction mechanism is primarily responsible for the downstream evolution of the azimuthally deforming elliptic vortices and it is also modified by the initial vorticity distribution. The jet temperature is elevated to study the effects of nonconstant density, or nonhomogeneity, on the large-scale entrainment process. The nonhomogeneous elliptic jet entrains 30 percent more mass than a homogeneous elliptic jet and up to three times more mass than a nonhomogeneous axisymmetric jet throughout the first eight exit diameters downstream. The preferred mode forced case entrains approximately as much mass as the natural case verifying that vortex self-induction is responsible for mass entrainment in small aspect-ratio asymmetric jets and that vortex merging is a second order effect. The Peak-Valley-Counting technique identifies an asymmetric distribution of small-scale structures primarily in the minor axis region of the natural elliptic jet with maxima occurring just downstream of the toroidal vortex cores. The preferred mode forced case induces a more symmetric distribution of small scales throughout the vortex cores and a 25 percent increase in the total small-scale population over the natural case. Small-scale distributions in the natural and forced elliptic jet correlate well to measured cones of combustion activity in chemically reacting shear flows. Therefore, the control of large- and small-scale mixing processes in a subsonic jet may be passively enhanced by asymmetric nozzle geometry and actively enhanced by preferred mode forcing. Dissert. Abstr.

A PRIORI TESTS OF LARGE EDDY SIMULATION OF THE COMPRESSIBLE PLANE MIXING LAYER
A. W. Vreman, Bernard J. Geurts, and J. G. M. Kuerten 12 Aug. 1993 50 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0169-2690)
(MEMO-1152; ETN-94-95726) Avail: CASI HC A03

Three important aspects for the assessment of the possibilities of Large Eddy Simulation (LES) of compressible flow are investigated. In particular the magnitude of all subgrid terms, the role of the discretization errors, and the correlation of the turbulent stress tensor with several subgrid models are studied. The basis of the investigation is a Direct Numerical Simulation (DNS) of the two and three dimensional compressible mixing layers using a finite volume method on a sufficiently fine grid. With respect to the first aspect, the exact filtered Navier-Stokes equations are derived and all terms are classified according to their order of magnitude. It is found that the pressure dilatation subgrid term in the filtered energy equation, which is usually neglected in the modeling practice, is as large as the pressure velocity subgrid term, which in general is modeled. The second aspect yields the result that second and fourth order accurate spatial discretization methods give rise to discretization errors which are larger than the corresponding subgrid terms if the ratio between the filter width and the grid spacing is close to one. Even if an exact representation for the subgrid scale contributions is assumed, LES is accurate only if this ratio is sufficiently larger than one. The turbulent stress tensor is investigated in more detail. A priori tests of subgrid models for this tensor yield poor correlations for Smagorinsky's model, which is purely dissipative, while the non-eddy viscosity models considered correlate considerably better. THE EFFECT OF AN AXIAL FLOW COMPONENT ON A CIRCULAR CYLINDER WAKE Ph.D. Thesis
Christine Gladding Lewis 1993 130 p
Avail: Univ. Microfilms Order No. DA9317509

A series of experiments were conducted to determine what effect a variation in the level of streamwise vorticity would have on the wake of a bluff body. These experiments investigate changes in wake dynamics caused by the introduction of a steady spanwise component of flow, which creates a steady influx of streamwise vorticity. To accomplish this, a cylinder in a uniform flow field is suddenly moved at constant velocity in the spanwise direction. The steady state flow condition is studied. The control cylinder technique is used to control the end conditions, to make the unperturbed flow parallel. Two primary modes of shedding are observed in the laminar cylinder wake, depending on the ratio of the axial cylinder velocity to the uniform flow velocity (V/U). For ratios of V/U less than four, oblique laminar shedding occurs. The direction and angle of the oblique shedding are controlled by the sign and magnitude of the ratio V/U. For larger ratios of V/U, shedding occurs in the form of trailing vortices. At a critical ratio of V/U, the vortex sheet appears to breakdown, and spectra are completely broadband. The steady-state motion can be compared, via Galilean transformation, to that of the yawed cylinder in a steady flow. Oblique shedding and trailing vortices have also been observed in yawed cylinder wakes. The relationship between shedding angle, frequency, wavelength, mean vorticity, and V/U is discussed. These results are compared to relationships found to occur in naturally occurring oblique shedding and to yawed cylinder results. Dissert. Abstr.

RESPONSE OF WALL TURBULENCE TO HIGH FREQUENCY STREAMWISE AND SPANWISE OSCILLATIONS Ph.D. Thesis
Wen-Je Jung 1993 200 p
Avail: Univ. Microfilms Order No. DA9319555

In an attempt to gain a better understanding of the dynamics of nonequilibrium turbulent wall flows, the response of wall turbulence to two classes of perturbations, namely, streamwise oscillations and spanwise oscillations, has been investigated by direct numerical simulation. Nondimensional periods of oscillation, T(sub osc)(sup +) = T(sub osc) u(sub tau)(exp 2)/nu, ranging from 25 to 2000 and amplitudes of oscillation ranging from 30 to 80 percent have been studied. Significant suppression of turbulence is observed with spanwise oscillations at T(sub osc)(sup +) = 100, which is accompanied by reductions of 60 percent in the overall turbulence production and 40 percent in the turbulent drag. Analysis of the dynamics of near-wall turbulence structures reveals that these reductions are due to a continual shift of near wall streamwise vortices relative to the wall layer streaks. In the case of streamwise oscillations, no net reduction was observed at any of the frequencies investigated. The dynamics of the flow in the presence of both classes of oscillations has been classified in terms of the value of the nondimensional periods of oscillation T(sub osc)(sup +). Dissert. Abstr.

A SOLUTION ADAPTIVE STRUCTURED-UNSTRUCTURED GRID PROCEDURE FOR UNSTEADY FLOWS Ph.D. Thesis
Sanjay R. Mathur 1993 112 p
Avail: Univ. Microfilms Order No. DA9321195

A solution adaptive hybrid grid method for the computation of 2-D, unsteady flows is presented. The method is capable of handling multiple component, complex geometries in relative motion, such as those encountered in turbomachinery analysis. The numerical approach uses a hybrid structured-unstructured zonal grid topology along with modeling equations and solution techniques that are most appropriate in the individual domains, thus, combining the advantages of both structured and unstructured grid methods. The viscous flow region in the immediate vicinity of the airfoils is resolved using a third order accurate, implicit, upwind solution of the Navier-Stokes equations on structured, O-type grids. Explicit solutions of the Euler equations are obtained in the rest of the domain that consists of an unstructured mesh made up of triangular cells. The use of both central- and upwind-difference flux schemes is investigated for the unstructured domains. Methodologies for accurate, conservative transfer of information at the interface between the structured and unstructured domains as well as that between two unstructured grid regions. Both time-averaged and time-resolved results are presented for test cases and are compared with available experimental data. The quality of the results obtained by the present method is comparable with those obtained by methods based on fully structured grids. Calculations performed using the solution adaptation capabilities are also presented. Dissert. Abstr.

ON THE STRUCTURE AND STABILITY OF SLENDER VISCOUS VORTICES Ph.D. Thesis
Ernst Wilhelm Mayer 1993 329 p
Avail: Univ. Microfilms Order No. DA9319584

The phenomenon of vortex breakdown, in which the flow near the axis of a rotating fluid suffers a sudden disruption, was first observed in the late 1950's. Despite having been the subject of intensive research since then, a fundamental understanding of the phenomenon has not yet been achieved. This thesis is an attempt at achieving such by way of a unified approach to each aspect which may be involved, the working hypothesis being that breakdown may best be understood as a nonlinear evolution problem. Treated in detail are the first two steps in such a program, which are first to understand the structure of the steady flows which may give rise to breakdown and then to investigate their stability. A family of similarity solutions to the Navier-Stokes equations, modeling the flows in leading-edge-type vortices, is presented. These solutions show a strong retardation of the axial flow in the core when the flow is subject to an adverse axial pressure gradient. The stability of several types of swirling base flows to 3-D disturbances is studied, revealing a rich variety of neutral and exponentially growing eigenmodes of both an inviscid and viscous character. The above axial retardation is also shown to be capable of inducing a linear instability of the flow, indicating the possibility of a secondary instability phenomenon. Implications of these results for the study of the full breakdown itself are discussed. Dissert. Abstr.

N94-31219 Massachusetts Inst. of Tech., Cambridge.
ON WAVE INTERACTIONS OF ROTATIONAL AND IRROTATIONAL FLOWS Ph.D. Thesis
Qingyuan Lu 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

This thesis takes rotationality into account in the classical water wave problem and centers on the wave interactions of rotational and irrotational flows for an inviscid fluid. The rotational stability of irrotational waves is analyzed. The Cauchy solution of a mean perturbed vorticity equation is obtained for a basic flow consisting two plane waves, and it is shown that rotational perturbations experience algebraic growth. The stability characteristics of the basic flow consisting of a gravity wave and a weak parallel shear flow are also explored. A Rayleigh-like equation for the normal velocity perturbation is derived. It is shown that the eigenvalues of this equation are complex for a large class of basic flows indicating that the existing weak shear flow can destabilize the gravity waves. Furthermore, a resonant triad consisting of a pair of gravity waves with equal wave lengths and a third component of a steady rotational flow is studied. A system of coupled nonlinear equations for the surface wave amplitudes and the rotational flow field has been derived. Thereafter, the rotational medium is treated as passive. Here it is found that there are two distinct effects of a rotational medium on gravity waves. The first effect is the wave scattering mechanism by the normal vorticity of the rotational flow. The other is an instability mechanism caused by the normal velocity of the rotational flow. This instability indicates that the incident surface waves may lose coherence and therefore cannot survive in a rotational medium. This may offer a partial explanation of the observed attenuation of waves in distant ship wakes. The analysis has also been extended to the interfacial waves of a two layered flow in the presence of rotationality.

A FULLY TWO-DIMENSIONAL, NON-OSCILLATORY ADVECTION SCHEME FOR MOMENTUM AND SCALAR TRANSPORT EQUATIONS
Elias Valur Holm 17 Nov. 1993 63 p
(ISSN 0349-0467)
(DM-66; ETN-94-95880) Avail: CASI HC A04/MF A01

The advection scheme developed is a fully two dimensional and nonoscillatory extension of the one dimensional Crowley type mass conservative schemes. The fully two dimensional scheme includes new cell to cell fluxes directed along the local flow direction, and the distribution of the advected variable within each cell is approximated by a fully two dimensional polynomial. Compared to the standard timesplit approach, the fully two dimensional approach is an order of magnitude more computationally effective in our tests. Furthermore, it removes the instability associated with the use of the standard timesplit approach in deformational flow. It is also directly applicable to momentum advection in, for example, incompressible flows. A problem with the application of the present scheme to momentum advection is that kinetic energy and enstrophy are dissipated too quickly when the solution is underresolved. ESA

COMPUTATIONAL STUDY OF SINGLE-EXPANSION-RAMP NOZZLES WITH EXTERNAL BURNING
Shaye Yungster and Charles J. Trefny Apr. 1992 28 p Presented at the 32nd Aerospace Sciences Meeting, Reno, NV, 10-13 Jan. 1994
(Contract NCC3-233; RTOP 505-90-5R)
(NASA-TM-106550; ICOMP-94-5; E-8702; NAS 1.15:106550; AIAA Paper 94-0024) Copyright Avail: CASI HC A03/MF A01

A computational investigation of the effects of external burning on the performance of single expansion ramp nozzles (SERN) operating at transonic speeds is presented. The study focuses on the effects of external heat addition and introduces a simplified injection and mixing model based on a control volume analysis. This simplified model permits parametric and scaling studies that would have been impossible to conduct with a detailed CFD analysis. The CFD model is validated by comparing the computed pressure

distribution and thrust forces, for several nozzle configurations, with experimental data. Specific impulse calculations are also presented which indicate that external burning performance can be superior to other methods of thrust augmentation at transonic speeds. The effects of injection fuel pressure and nozzle pressure ratio on the performance of SERN nozzles with external burning are described. The results show trends similar to those reported in the experimental study, and provide additional information that complements the experimental data, improving our understanding of external burning flowfields. A study of the effect of scale is also presented. The results indicate that combustion kinetics do not make the flowfield sensitive to scale. Author

NUMERICAL ANALYSIS OF SINGLE-VORTEX/FREE-SURFACE INTERACTION M.S. Thesis
Craig F. Merrill Dec. 1993 87 p
(AD-A276462) Avail: CASI HC A05/MF A01

The interaction of a single Lamb vortex with a free surface is analyzed numerically through the use of a finite-difference technique. The individual effects of gravity, viscosity, and surface tension are investigated within the range of the applicability of the phenomenon and the code used. The vortex is allowed to build up to its full strength in a relatively small time and then the evolution of the free surface, streamlines, and other details of the flow are calculated. The results have shown that the smaller the proximity of the vortex to the free surface, the larger the scar produced on its down-wash side. The effect of the surface tension is to reduce the amplitude of the free surface elevation. The viscous effects appear to be relatively small even though the calculations are, out of necessity, confined to a limited range of the governing parameters, as in all finite difference calculations. OSCILLATIONS IN PISTON-DRIVEN SHEAR FLOW OF A NON-NEWTONIAN FLUID Summary Report
David S. Malkus, John A. Nohel, and Bradley J. Plohr Feb. 1994 17 p
(Contracts DAAL03-91-C-0027; DAAL03-92-G-0185)
(AD-A276472; CMS-TSR-94-8) Avail: CASI HC A03/MF A01

In recent experiments on piston-driven shear flow of a highly elastic and very viscous non-Newtonian fluid, Lim and Schowalter observed nearly periodic oscillations in the particle velocity at the channel wall for particular values of the constant volumetric flow rate. Such periodicity has been characterized as a 'stick/slip' phenomenon caused by the failure of the fluid to adhere to the wall. We suggest an alternative explanation for these oscillations using a dynamic mathematical model based on the Johnson-Segalman-Oldroyd constitutive relation, the key feature of which is a non-monotonic relationship between steady shear stress and strain rate. The resulting three-dimensional equations of motion and stress are reduced to one space dimension, consistent with experimental results. In the inertialess approximation, the equations governing the flow can be viewed as a continuous family of quadratic ordinary differential equations coupled by the non-local constraint that fixes the volumetric flow rate. Varying the flow rate, the numerical simulation of solutions to this system exhibits transitions to and from a regime with persistent oscillations that compare favorably with the Lim-Schowalter observations. When the time-asymptotic behavior is cyclic, large shear strain rates are observed in a thin but macroscopic layer near the wall. The transitions are explained using spectral analysis of the linear (infinite dimensional) operator resulting from linearization of the quadratic system about a discontinuous steady state with a jump discontinuity in the stress components. The persistent oscillations arise as a Hopf bifurcation to periodic orbits as the volumetric flow rate is increased beyond a critical value. DTIC

ANALYSIS OF THE PHOTODIODE BOUNDARY LAYER TRANSITION INDICATOR
D. W. Kuntz, A. C. Wilken, and J. L. Payne 1994 15 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 11-14 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005311; SAND-93-1274C; AIAA Paper 94-0454; CONF-940152-2)
Avail: CASI HC A03/MF A01

The photodiode transition indicator is a device which has been successfully used to determine the onset of boundary layer transition on numerous hypersonic flight vehicles. The exact source of the electromagnetic radiation detected by the photodiode at transition was not understood. In some cases early saturation of the device occurred, and the device failed to detect transition. Analyses have been performed to determine the source of the radiation producing the photodiode signal. The results of these analyses indicate that the most likely source of the radiation is blackbody emission from the heatshield material bordering the quartz window of the device. Good agreement between flight data and calculations based on this radiation source has been obtained. Analyses also indicate that the most probable source of the radiation causing early saturation is blackbody radiation from carbon particles which break away from the nosetip during the ablation process. (AD-A275917; EFD-003) Avail: CASI HC A03/MF A01

The research conducted has two components. In the first part, a model that deals with turbulent mixing across sharp density interfaces subjected to homogeneous turbulence was developed. The analysis was essentially based on the rapid distortion theory approach of Hunt, which reckon on the empirical observation that the dissipation rate of turbulent kinetic energy above an interface is independent on the height z. The homogeneous turbulence was modeled using the classical von Karman spectra and the interfacial motions were assumed to be governed by the linear internal-wave equations. It was further assumed that the first mode of internal waves governs the interfacial motions, thus simplifying the interfacial boundary conditions; the latter have been a major difficulty in modeling fluid motions near sharp density interfaces. The effect of strong acoustic waves on the breakup and dispersion of cylindrical liquid jets is considered with regard to combustion instabilities of liquid injection burners. An experimental study showed that a strong acoustic excitation modifies jet stability at low injection velocities (by reduction of the breakup length). This phenomenon, which exhibits saturation and threshold effects, is especially sensitive to excitation intensity. A linearized analysis of forced instabilities of a liquid jet shows that turbulence induced by acoustics, which appears for all breakup modes, can explain the observations with low speed injection. The literature shows that a strong acoustic excitation presents dispersive and agglomeration effects on a particle. Previous works include physical description and numerical methods, which might describe the turbulent dispersion of particles and turbulence induced by strong acoustic excitation. These points remain to be improved. Numerical simulations, made without consideration of turbulence, confirmed the experimentally observed dispersive effects of transverse waves applied on a cylindrical jet. This study can provide a basis for future investigations where quantitative experimental results will necessarily be obtained. ESA

RESEARCH IN MARINE BOUNDARY LAYER INTERMITTENCY
John C. Wyngaard 20 Jan. 1994 3 p
(AD-A276076) Avail: CASI HC A01/MF A01

Wind-tunnel calibrations of turbulent-pressure sensors usually reveal deviations from ideal response. These deviations are typically reported in dimensional form (e.g., in microbars) or as a fraction of the dynamic

pressure. Neither presentation gives a direct indication of the reliability of pressure statistics measured in a turbulent flow. We derive a general response equation for a turbulent-pressure probe. The coefficients in the equation are obtainable from standard wind-tunnel calibration results. The form of the response equation makes it straightforward to relate the errors in measured pressure statistics of the turbulence. We demonstrate this by evaluating the reliability of measurements of some important pressure covariances, including the pressure-transport term in the turbulent kinetic energy (TKE) budget in the unstable surface layer. The preliminary finding is that the Nishiyama-Bedard sensor is capable of measuring pressure transport of TKE there to within 10-20%. DTIC

The initial report on the 'unified waves model' describes a procedure to compute water wave propagation over long distances accurately at low cost, and for a wide variety of physical situations. This report outlines recent developments that extend its capabilities. These involve: (1) inclusion of a variable depth, (2) addition of a wavemaker, and (3) the ability to send steady nonuniform flows through the computational domain. Examples of calculations employing the new capabilities are given. DTIC

THREE-DIMENSIONAL VELOCITY MEASUREMENTS ON A 6:1 PROLATE SPHEROID AT 10 DEG ANGLE OF ATTACK
Christopher J. Chesnakas, Roger L. Simpson, and Michael M. Madden 18 Jan. 1994 230 p Revised
(Contract N00014-91-J-1732)
(AD-A276485; VPI-AOE-202-Rev) Avail: CASI HC A11/MF A03

The flow in the cross flow separation region of a 6:1 prolate spheroid at 10 degrees angle of attack, Re(sub L) = 4.20 x 10(exp 6), was investigated using a novel three dimensional fiber optic laser doppler velocimeter (LDV). The probe was used to measure three simultaneous, orthogonal velocity components from within the model. The design and operation of this LDV probe is described and velocity, Reynolds stress, and velocity triple product measurements are presented from the inner boundary layer through the boundary layer edge. A model developed to simulate reactive turbulent flows with a noninfinitely fast chemistry using a joint Probability Density Function (PDF) is described. It is very complicated to solve the joint velocity and concentration PDF time variation equation analytically or numerically. But the problem can be simplified by integrating this equation in the velocity space. The result is a hybrid Eulerian-Lagrangian probabilistic approximation. The equation is then simulated by a Monte-Carlo method. In this equation, the small scale mixing phenomenon is represented by a model. The new model was compared with conventional mean exchange models in the case of a thermal mixing layer and a reactive mixing layer. The computation results were promising. It was demonstrated that the new model could be used for complex industrial two dimensional (2D) axisymmetric configurations (the bluff body) and 3D configuration (DEXTRE combustion chamber). ESA

VISCOUS LIMITER FUNCTIONS FOR MODEL CONVECTION-DIFFUSION EQUATIONS
E. F. Toro May 1993 23 p Revised
(Cranfield-Aero-9103; ISBN-1-871564-60-3; ETN-94-96068) Avail: CASI HC A03/MF A01; Cranfield Univ. of Technology, Coll. of Aeronautics, Cranfield, Bedford MK43 0AL, England, HC

Viscous Limiter Functions (VLF's), for use with Riemann problem based shock capturing methods as applied to viscous flows, are presented. In particular, viscous flux limiters are derived. The analysis pertains to a linear convection diffusion model equation. These VLF's combine the physical viscosity, the role of which is maximized, with numerical viscosity, whose role is minimized, to capture oscillation free solutions to convection diffusion equations. Assessment of the concepts presented is carried out through numerical experiments on linear and nonlinear model equations with exact solutions. ESA

COMPUTATIONAL RADIATIVE HEAT TRANSFER IN HOMOGENEOUS AND NONHOMOGENEOUS NONSCATTERING MEDIA Ph.D. Thesis
Perry Lee Fuehrer 1993 208 p
Avail: Univ. Microfilms Order No. DA9315778

A computational methodology was developed for calculating radiative heat transfer in gaseous nonhomogeneous nonscattering media with complex emission and absorption spectra. The technique can be used in both equilibrium and nonequilibrium situations. Test cases applied to an Aeroassisted Orbital Transfer Vehicle (AOTV) were investigated, and results are presented herein. Nonequilibrium compositions and temperatures were taken from NASA-Langley three-dimensional hypersonic flowfield calculations that include real-gas effects and finite-rate chemical kinetics. This output was used as input to the NASA-Ames NEQAIR code to compute local values of spectral emission and absorption coefficients. For each spatial point considered, total (spectrally integrated) properties were computed, and these total properties were used to make the radiation calculations. Use of total properties was found to yield remarkably accurate values of total intensity when compared to exact results for the cases examined in the AOTV flowfield. Results are presented for three markedly different lines of sight along with heat flux calculations for six receiver locations. Also an examination of using the technique in a differential formulation for the calculation of the gradient of intensity at a point is conducted. A more accurate intensity and gradient of intensity calculation is made assuming linear spatial variations of spectral emission and absorption coefficients. The method is also compared to exact integration over the line structure of the 2143 cm(exp -1) band of CO for nonhomogeneous paths. These results are compared to calculations using the exponential wide-band model along with either the nonhomogeneous wide-band scaling or the transmission-path-adjustment algorithm. Finally, three nonhomogeneous lines of sight in water vapor were investigated using the exponential wide-band model. Water vapor was chosen due to its five bands which are spread throughout the spectrum. Comparison is made between wide-band scaling and the transmission path-adjustment method. Dissert. Abstr.

FLUID-STRUCTURE INTERACTION IN CASE OF WATER HAMMER WITH CAVITATION Ph.D. Thesis
A. S. Tijsseling 29 Jun. 1993 246 p Prepared in cooperation with Waterloopkundig Lab., Delft, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148277) Avail: CASI HC A11

The transient behavior of liquid-filled pipe systems is studied. The time scale is acoustic. Pressure waves in the liquid, and axial, lateral, and torsional stress waves in the pipes are the dominant phenomena. The phenomena in the liquid (water hammer) and the phenomena in the pipe system (structural dynamic) influence each other if significant radial and axial pipe motions occur. When, in addition, the dynamic pressure drops to the vapor pressure, vapor bubbles will form in the liquid (cavitation). The major new element of the present work is in the simultaneous occurrence of fluid-structure interaction (FSI) and cavitation, which is investigated both theoretically and experimentally. An extensive review of literature on the subject is given. One dimensional basic equations are obtained by integration of general three dimensional equations for fluid dynamics and structural

linear elasticity. Three FSI-mechanisms (junction, Poisson, and friction-coupling) are taken into account. The governing equations, formulated as a hyperbolic set of fourteen first-order partial differential equations, are solved by the method of characteristics. Vapor cavitation is numerically simulated by the relatively simple concentrated cavity model. NTIS

CELL-VERTEX DISCRETISATION OF THE DRIVEN CAVITY FLOW WITHOUT ARTIFICIAL DIFFUSION
F. O. O. Wagener Jun. 1993 32 p
(W-9317; ETN-94-96178) Avail: CASI HC A03/MF A01

To solve the compressible Navier-Stokes equations in a driven cavity test case, traditional cell vertex discretization using the midpoint rule and artificial diffusion did not produce a steady state solution where it should. This is due to a loose treatment of the boundary. A more satisfactory and working alternative is proposed, which moreover has the virtue of making artificial diffusion superfluous. ESA

Incompressible steady state turbulent flows are simulated numerically using a finite element method. Since the direct numerical simulation of turbulent behavior of fluids is beyond the capability of present day computers, the object of the study was to evaluate the suitability of algebraic turbulence models for computation of turbulent flows. An algebraic turbulence model using a two-layer concept was implemented into a generic incompressible Navier-Stokes solver. The spatial discretization of the flow field is realized by the finite element method of the averaged Navier-Stokes equations. To satisfy mass conservation, an augmented Lagrangian implementation of Uzawa's algorithm is used. It is known that algebraic and two-equation turbulence models require knowledge of the normal distance to the wall. A technique allowing the evaluation of this normal distance on an unstructured grid is evaluated and implemented. The algorithmic requirements and the appropriate strategy of resolution are determined for the considered model, and the methodology is applied in both two and three dimensional configurations. Simulation results are presented for turbulent flow around a NACA0012 airfoil and on a flat plane. Author (CISTI)

A mathematical model that solves the pressure velocity form of the steady state Navier-Stokes equations is described. This finite element model uses the penalty function method to remove one degree of freedom at every computational node. In addition, a new approach is introduced which renders the matrix in the resulting set of algebraic equations symmetric and banded. This approach is named the linearized source term method. After a survey of different turbulence closure models, the mathematical model coupled with an algebraic closure model is applied to a practical case study. Since its domain of applicability is not restricted to the Navier-Stokes equation, the linearized source term method is then applied to the resolution of another nonlinear equation: a simplified form of a turbulence closure model. Finite element vorticity-based methods are applied to the analysis of viscous flows. Analysis is carried out in terms of a stream function vorticity formulation for two dimensional (2D) flows and a velocity vorticity formulation for 2D and three dimensional (3D) flows. Second order equations are obtained for the variables and the discretization is based on the weak-Galerkin weighted residual method. The proposed stream function vorticity approach reverses the traditional imposition of wall boundary conditions. The finite element method is used to naturally impose the no-slip condition on the stream function equation accurate for complex geometries. This method is extended to 2D subsonic external lifting flow. The unknown stream function value on the airfoil for lifting flow is obtained by enforcing a continuous pressure distribution over the entire airfoil. This is imposed naturally through the finite element discretized vorticity transport equation. The finite element weak-Galerkin method used in the proposed velocity vorticity scheme is extended to 2D and 3D subsonic internal flow. A new accurate wall vorticity boundary condition is also proposed. The stream function and vorticity or the velocity and vorticity are solved simultaneously using a Newton method. No artificial viscosity was required to stabilize the iteration algorithm. Author (CISTI)

MICROMECHANICS AND EFFECTIVE PROPERTIES OF PARTICULATE COMPOSITES AND FLUID SUSPENSIONS Ph.D. Thesis
Tsung-Muh Chen 1993 161 p
Avail: Univ. Microfilms Order No. DA9328076

It is well-known that the addition to a homogeneous continuum of a second particulate material having different physical properties can greatly alter the effective properties of the resulting two-phase system. In general, the effective properties of the medium will depend on the physical properties of both constituent phases, as well as the volume fraction, geometry, shape, and spatial distribution of the dispersed particles. The term 'effective

property' usually implies that a multi-phase system is being approximated as a macroscopically homogeneous continuum. This approximation is valid when a multi-phase system is viewed on a representative length scale, or more specifically the representative averaging domain, can only be defined on the basis of an assumption about the macroscopic homogeneity of a multi-phase system; that is, any volume-averaged property remains the same regardless of the spatial position of an averaging domain. In the first part of this study, attention is focused on the overall behavior of particulate composites. A general framework emanating from the eigenstrain concept introduced by Eshelby is presented for determining the effective elastic moduli of two-phase composites. Subsequently, a complete formulation of the many-particle interaction problem is given, and a new approach avoiding the problem of non-absolute convergence is also presented. Some existing models are then recovered from the far-field solution, in which the interaction between neighboring particles is neglected, due to mathematical analogy, the effective viscosity of fluid suspension is obtained from the results of particulate composites as the limiting case of an incompressible matrix containing either rigid spheres or spherical cavities. The present framework is further combined with phenomenological plastic analysis to investigate the overall elasto-(visco-)plastic behavior of particulate composites. Finally, an analogous framework for the determination of effective conductivities of random dispersions of rigid-spheres is presented. Dissert. Abstr.

SURFACE FLUXES OF TRACE GASES DERIVED FROM CONVECTIVE-LAYER PROFILES Ph.D. Thesis
Kenneth J. Davis 1992 291 p
Avail: Univ. Microfilms Order No. DA9318086

Nonlocal gradient and variance functions relating the surface and entrainment fluxes of a passive scalar to the mean mixing ratio and variance profiles in the cloud-free, convective boundary layer have been determined from large eddy simulations. These functions can be used to calculate the surface and entrainment fluxes of trace gases over a large area, given profile measurements within the convective boundary layer. This dissertation develops the convective layer gradient technique for estimating fluxes and demonstrates two potentially valuable applications. An attempt is made to verify the large eddy simulation gradient functions with aircraft observations from the First ISLSCP Field Experiment and the San Joaquin Valley Air Quality Study. Results show general agreement with the simulated gradient functions but precise comparison is made difficult by scatter in the aircraft derived functions. The gradient functions are used to estimate forest emissions of nonmethane hydrocarbons using tethered balloon profiles. Mean emission estimates from profiles collected during the Amazon Boundary Layer Experiment 2A and the Rural Oxidants in the Southern Environment 1 experiment show good agreement with estimates made from budget arguments. Daytime isoprene emissions from the dry season Amazon are estimated to be 3860 +/- 1380 microgram m(exp -2) hr(exp -1). Summer, daytime isoprene emissions from an Alabama pine-oak forest are estimated to be 4040 +/- 3200 microgram m(exp -2) hr(exp -1), alpha-pinene emissions 1750 +/- 1060 microgram m(exp -2) hr(exp -1), and beta-pinene emissions 770 +/- 560 microgram m(exp -2) hr(exp -1). Fluxes from individual profiles are very scattered and expected diurnal cycles in emission rates are not distinguishable. This technique provides a valuable means of measuring biogenic hydrocarbon emissions, a precursor to photochemical ozone production. The convective layer gradient technique holds the potential for remote estimation of surface fluxes over large areas using remote profiling technology, such as differential absorption lidar (DIAL). An attempt to estimate ozone deposition rates using an ozone DIAL system was unsuccessful. The minimum signal to noise ratio for successful ozone deposition estimates using this DIAL system and the convective layer gradient technique was derived and is less than the signal to noise level in the analyzed DIAL observations. Dissert. Abstr.

INCOMPRESSIBLE VISCOUS FLOW IN TUBES WITH OCCLUSIONS Ph.D. Thesis
Huaxiong Huang 1991 249 p
(ISBN-0-315-75467-2) Avail: Univ. Microfilms Order No. DANN75467

Viscous, incompressible flow in tubes with partial occlusion is investigated using numerical and experimental procedures. The study is related to the problem of atherosclerosis, one of the most common diseases of the circulatory system. One of the computational difficulties in solving the incompressible Navier-Stokes equations is the lack of pressure or vorticity boundary conditions. A finite difference approach, referred to as the interior constraint (IC) method, is proposed to resolve this difficulty. As a general numerical method, it is formulated for both the stream function-vorticity and primitive (physical) variable formulations. The procedure is explained using a one dimensional model with extensive numerical tests presented for two dimensional cases, including flow in a driven cavity and flow over a backward facing step. Results are obtained with second-order accuracy. Next, the IC method is applied to flow in a tube with an occlusion, which is used as the model for blood flow in stenosed arteries in the study of the pathology of atherosclerosis. Numerical results are obtained for both steady and pulsatile flows. Results are compared with those of SIMPLE, one of the commercially available numerical algorithms. The pulsatile flow study revealed several interesting new features. It suggested that the high shear stress is not likely to initiate atherosclerosis lesions. The recirculation region, which is a prominent feature of the unsteady flow, is more likely to cause the initiation and development of the disease. Experimental measurements for steady flow complement the numerical study and show qualitative agreement. Dissert. Abstr.

AN ADAPTIVE METHOD FOR THE EXACT RESOLUTION OF SHOCK WAVES AND CONTACT DISCONTINUITIES M.S. Thesis [UNE METHODE ADAPTIVE POUR LA RESOLUTION EXACTE DES ONDES DE CHOC ET DES DISCONTINUITES DE CONTACT]
Marius Paraschivoiu Jul. 1993 146 p In FRENCH
(ISBN-0-315-86498-2; CTN-94-61202) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A methodology is presented which allows improved resolution of discontinuities that appear when solving the Euler equations. The basic principle is to take full advantage of Roe's upwind difference scheme, which is able to solve discontinuities with exact resolution when a grid line is oriented and located along the discontinuity. Based on this property, a technique is suggested that moves and adapts the grid to align and position an element interface on the discontinuities. For unsteady discontinuities, the exact solution is obtained when the cell interface moves at the same speed as the discontinuities. The shock waves and contact discontinuities are located using a wave model based on the properties of the acoustic waves, the entropy wave, and the shear wave. The neighboring mesh is then moved on the shocks or slip lines using the speed of those waves. An algorithm is implemented in a two-dimensional finite volume solver on unstructured triangular mesh. Mass, momentum, and energy fluxes at the interface are solved using an approximate Riemann solver based on Roe's scheme. The method is proven to find the exact solution for analytical test cases and to improve drastically the sharpness of the discontinuities for more complex geometries. For unsteady flows, the shock location is captured with great accuracy at any time position. Author (CISTI)

COMPUTATIONAL STUDY OF SIMULTANEOUS HEAT AND MASS TRANSFER IN TURBULENT SEPARATED FLOWS Ph.D. Thesis
Abdelghani Zigh 1993 196 p
Avail: Univ. Microfilms Order No. DA9328536

Many real problems of engineering interest contain regions of highly turbulent flow that exhibit separation and recirculation. An understanding of heat and mass transfer characteristics in these regions is of considerable importance in industrial practice. In this study, a finite volume numerical method is developed and utilized for the prediction and analysis of flow over a cascade of turbine blades involving simultaneous heat and mass transfer. The renormalization group (RNG) approach based nonlinear k-epsilon turbulence model is utilized to describe the flow field. The computational procedure involves the simultaneous solution of the time averaged equations of motion, heat, mass, and turbulent kinetic energy and its dissipation in generalized body-fitted coordinates. The first part of this study is aimed at the development of an algorithm and its validation through the analysis of a number of benchmark test cases. These include the turbulent flow with and without heat transfer downstream of an abrupt channel expansion, turbulent flows in the wake of a flat plate and isolated airfoils, and flow past airfoil cascades with and without trailing edge separation. The results are compared with the available experimental data and shown to be in excellent agreement. The second part involved parametric

study of the transpiration cooling of a turbine blade cascade. Flow past turbine blade cascades with simultaneous heat and mass transfer are analyzed for Reynolds numbers from 5 x 10(exp 5) to 2 x 10(exp 6) and flow angles from -30 deg to 55 deg. The effects of the separation were appreciable in the suction side and the Nusselt and Sherwood numbers in the separation zone reached a maximum at the reattachment point. It is found that the behavior of the separated shear layer plays an important part upon the heat transfer in the recirculation zone. Correlations between the average and the maximum Nusselt numbers and the Reynolds number as well as the average and the maximum Sherwood numbers and the Reynolds number suitable for application to turbine blades are developed. The last part of this study involved the prediction of stalled flow in axial compressor cascades. The performance of the algorithm is analyzed and the results from the present study are compared with the available experimental and computational results. Dissert. Abstr.

STEADY THERMAL CONVECTION IN MULTIPLE LIQUID LAYERS Ph.D. Thesis
Ajay Prakash 1993 376 p
Avail: Univ. Microfilms Order No. DA9320471

Convective flow in multiple liquid layers confined in a rectangular cavity is investigated using analytical, numerical, and experimental techniques. The cavity is subjected to differential heating, either parallel to or perpendicular to the interfaces between liquid layers. Thermal convection in the liquid layers results from buoyancy and from temperature induced changes in interfacial tension. Since the genesis of buoyancy is gravity, buoyancy effects are significantly reduced in a low-gravity environment. Definition of a space flight experiment aboard the upcoming IML-2 mission along with validation of fluid dynamical models with ground based experimentation are the objectives of this investigation. Flow in shallow cavities subjected to differential heating parallel to the interfaces is analytically investigated using the method of matched asymptotic expansions. Natural convection, without the influence of thermocapillary forces, is investigated in two and three layer systems. In low-gravity environments, thermocapillary convection with deformable interfaces is also studied. Ground based experiments to visualize the flow field are conducted. Particle streak line photography is used to visualize the flow. Particle displacement tracking is used to evaluate the velocity vector field, and holographic interferometry is used to visualize the temperature field. Numerical simulation is performed with the computer code FIDAP. Convection due to differential heating perpendicular to the interfaces is investigated using a linear stability analysis. Two and three layers of infinite horizontal extent are considered. Ground based experiments are conducted to visualize the temperature field in two and three layer systems confined in a box. Fluid dynamical models relying on mechanical coupling are experimentally validated for certain fluid combinations, while for other fluid combinations significant disparity is observed. An immobile interface is observed in the experiments, while the models predict a mobile interface. The discrepancy is attributed either to interfacial contamination in the form of molecular monolayers or to a very thin shear layer in the vicinity of the interface which could not be visualized. The existence of monolayers must be considered a real possibility for liquid combinations used in practical applications. A liquid combination exhibiting reasonable resistance to contaminant formation has been identified for the space flight experiment. Dissert. Abstr.

THERMOCAPILLARY CONVECTION IN EVAPORATING SESSILE DROPS (Videotape)
1986 Videotape: 28 min. 30 sec. playing time, in color, with sound (NASA-TM-109758; NONP-VT-94-9958) Avail: CASI VHS A01/BETA A22

The purpose of this video is to understand the effects of surface tension on fluid convection. The fluid system chosen is the liquid sessile droplet to show the importance in single crystal growth, the spray drying and cooling of metal, and the advance droplet radiators of the space stations radiators. A cross sectional representation of a hemispherical liquid droplet under ideal conditions is used to show internal fluid motion. A direct simulation of buoyancy-dominant convection and surface tension-dominant convection is graphically displayed. The clear differences between two mechanisms of fluid transport, thermocapillary convection, and bouncy dominant convection is illustrated. CASI

MULTIGRID DIAGONAL IMPLICIT SOLUTIONS FOR COMPRESSIBLE TURBULENT FLOWS AND THEIR EVALUATION Ph.D. Thesis
Rama Rajaraja Varma 1993 144 p
Avail: Univ. Microfilms Order No. DA9325308

A numerical scheme to solve the two dimensional Navier-Stokes equations is developed and applied to several compressible turbulent flows over airfoils. A method for evaluating the quality of these solutions is then developed and illustrated with representative examples. The distinguishing features of the numerical scheme are its implicitness for improving stability, the diagonalization of the matrices in the implicit operator for computational efficiency, and the implementation within a multigrid procedure for convergence acceleration. A finite volume approximation is used for spatial discretization of the governing equations to handle complicated geometries. Artificial dissipation is added in the form of an adaptive blend of second and fourth differences of the solution to maintain robustness and stability. The viscous terms are treated explicitly to maintain the diagonal form. Results of simulations of viscous transonic flows past airfoils are presented. The computed flow field quantities are compared with those from other computations and experiments to confirm the accuracy of the method. Comparisons of convergence rates are made to demonstrate the efficiency of the method. In solutions to the Navier-Stokes equations it is important that the added numerical dissipation does not overwhelm the real viscous dissipation. In order to verify this, it is necessary to be able to estimate quantitatively the effect of numerical dissipation. A method for estimating the integrated effect of numerical dissipation on solutions to the Navier-Stokes equations is developed in this dissertation. The method is based on integration of the momentum equations and the computation of corrections due to numerical dissipation to the drag integral. These corrections can then be considered as estimates of the error due to dissipation. Solutions to the Navier-Stokes equations for laminar and turbulent flows over airfoils are used to illustrate the method. The errors due to numerical dissipation are compared with the total numerical errors in the solutions. The effects of different boundary conditions on the numerical dissipation are evaluated, providing means of judging the quality of the solutions. Dissert. Abstr.

OBSERVATIONS OF TURBULENCE, INTERNAL WAVES AND BACKGROUND FLOWS: AN INQUIRY INTO THE RELATIONSHIPS BETWEEN SCALES OF MOTION Ph.D. Thesis
Kurt Lewis Polzin 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

Oceanic profiles of temperature, salinity, horizontal velocity, rate of dissipation of turbulent kinetic energy (epsilon) and rate of dissipation of thermal variance (chi) are used to examine the parameterization of turbulent mixing in the ocean due to internal waves. Observations from the far field of a seamount in a region of negligible large-scale flow were examined to address the issue of the buoyancy scaling of epsilon. These data exhibited large variations in background stratification with depth, but the internal wave characteristics were not substantially differentiable from the GM prescription. Data from an upper-ocean front, a warm core ring and a region of steep topography were analyzed in order to examine the parameter dependence of epsilon in internal wave fields which exhibited potentially nonstationary characteristics. Evidence was provided which implied the internal wave field in an upper ocean front was interacting with and modified by the background flow. Inhomogeneity and anisotropy of the internal wave field were noted in that data set. On the basis of a number of theoretical Richardson number probability distributions (Ri = N(sup 2)/S(sup 2), where S(sup 2) is the sum of the squared vertical derivatives of horizontal velocity), the nominal dissipation scaling of the Kunze et al. model was determined to be E(sup 2)N(sup 3). This scaling is altered to the observed epsilon similar to E(sup 2)N(sup 2) scaling by a statistical dependence between N(sup 2) and S(sup 2) which reduces the occurrence of supercritical Ri values. This statistical dependence is hypothesized to be an effect of the turbulent momentum and buoyancy fluxes on the internal wave shear and strain profiles caused by shear instability. The statistical dependence between N(sup 2) and S(sup 2) exhibited a buoyancy scaling which was interpreted

as resulting from the decreasing ratio between the time scale of the shear instability mechanism (T equivalent to 2(pi)/N) and the adiabatic time scale (T equivalent to 2(pi)/(Nf)(exp 1/2)) of the internal wave field (f is the Coriolis parameter). We argue that saturated spectral theories are valid only in the limit where a separation exists between the two time scales, i.e. for large N, low internal wave frequency content, and small f. These results have immediate implications for oceanic mixing driven by internal wave motions. Dissert. Abstr.

HOTWIRE MEASUREMENTS OF THE TURBULENT FLOW INTO A CASCADE OF CONTROLLED-DIFFUSION COMPRESSOR BLADES M.S. Thesis
Bryce E. Wakefield Dec. 1993 64 p
(AD-A277297) Avail: CASI HC A04/MF A01

Turbulence measurements near the leading edge of a compressor stator were made in a subsonic cascade wind tunnel with a hotwire system. Using a single hot-film probe, velocity and turbulence distortion data were obtained about the leading edge of the Controlled-Diffusion (CD) blades in order to verify Laser Doppler Velocimetry (LDV) data taken in earlier studies. Measurements were conducted at a Mach number of .25, a Reynolds number of 711,000, and an inlet flow angle of 48 deg. Turbulence profiles obtained in the pitch-wise direction were found to be in good agreement with previous LDV measurements. These data indicated a localized increase in turbulence around the leading edge due to the interaction of the free-shear layer with the inlet turbulence. This free-shear layer extends over the separation bubble, which forms on the suction side of the blades' leading edge. DTIC

ON AN ADAPTATION METHOD FOR DENSE, 2D, C-TYPE GRIDS M.S. Thesis
M. A. Vis Jun. 1993 61 p Prepared in cooperation with National Aerospace Lab.
(W-9321; ETN-94-96182) Avail: CASI HC A04/MF A01

The study of the practical application of an adaptive grid method for high resolution (dense), 2D (two dimensional), C type grids around aerofoils is presented. For testing, the method was applied to the adaptation of a grid used for the simulation of a viscous flow around the RAE2822 aerofoil. The method may be suitable for adapting high resolution grids. A NON-LOCAL MODEL FOR PREDICTION OF THE PROBABILITY DENSITY FUNCTION OF TURBULENT FLUCTUATIONS IN BOUNDARY-LAYER FLOWS Ph.D. Thesis
Michael John Brown 1993 151 p
Avail: Univ. Microfilms Order No. DA9320826

A mathematical model has been developed to predict the probability density function (pdf) and related statistical quantities of turbulent fluctuations in horizontally homogeneous boundary layer flows. The model is nonlocal, i.e., turbulent fluctuations are produced by vertical and longitudinal transport of fluid properties over finite distances from upstream positions. Fluid properties are assumed to be carried by fluid parcels. The likelihoods of parcel transport between two points and of property conservation during transport are determined using a point source dispersion model and a Lagrangian autocorrelation function, respectively. The model requires as input the mean vertical profile of the property being transported, as well as vertical profiles of the mean velocity, vertical mass eddy diffusivity, and Lagrangian time scale. Model assumptions have been tested by comparing model predictions with velocity measurements from a wind tunnel simulation of the neutral atmospheric boundary layer. The agreement between measured and model-predicted pdf's improved significantly when it was assumed that a parcel can take on a range of possible velocities, rather than the local mean value, when it mixes with the surrounding fluid. Model-predicted sigma(sub u) profiles were found to be sensitive to the form of the mean velocity, eddy diffusivity, and Lagrangian time scale profiles. With realistic input, however, model-predicted pdf and sigma(sub u) profiles were reasonably simulated. Model-predicted sigma(sub u) profiles collapsed onto one curve when scaled by u(sub *), decreased with height, and gave a surface value of sigma(sub u)/u(sub *) approximately 2.5. The model also predicted that sigma(sub u)/bar-U(z) should be an increasing function of z(sub 0), in agreement with field measurements. A method for predicting the Reynolds shear stress was proposed and preliminary results appear promising. Dissert. Abstr.

STUDIES IN PHYSICO-CHEMICAL HYDRODYNAMICS OF EXTENDED SYSTEMS
G. I. Sivashinsky 1993 16 p
(Contract DE-FG02-88ER-13822)
(DE94-006752; DOE/ER-13822/7) Avail: CASI HC A03/MF A01

The object of the proposed research program is a unified theoretical approach to the description of a variety of physico-chemical hydrodynamic systems characterized by a significant disparity between the spatial scales involved. By appropriately performed averaging over short scales, one may considerably simplify the original problem, sometimes even lowering its effective dimensionality, and thereby making the latter quite tractable either analytically or numerically. Specifically, the author plans to study: (1) the hydrodynamic aspects of flameholding and flammability in premixed gas flames, (2) large-scale structures in Rayleigh-Benard-Marangoni convection in nonreactive and reactive liquid layers, (3) nonlinear dynamics of interfacial instabilities dominated by viscosity effects, and (4) negative viscosity effects and formation of large-scale structures in liquid layers driven at small scales. SURFACE BOUNDARY CONDITIONS AND RELATED TECHNICAL ISSUES CONCERNING BURNETT EQUATIONS FOR 2-D HYPERSONIC FLOW Final Technical Report, 15 Nov. 1991 - 14 Nov. 1993
Xiao-Lin Zhong 14 Jan. 1994 21 p
(Contract F49620-92-J-0090)
(AD-A277322; AFOSR-94-0074TR) Avail: CASI HC A03/MF A01

Research on studying steady and transient rarefied hypersonic flow by using the Burnett equations and developing accurate and efficient numerical methods for both the Navier-Stokes and Burnett equations were conducted in three aspects: (1) A new method of formulating the additional boundary conditions for the Burnett equations was presented. The 2-D Burnett equations with first order slip conditions seem to be able to improve the Navier-Stokes equations in two dimensions in the continuum transition regime, though more validation work is needed for the Burnett equations. (2) The first Burnett solutions for axisymmetric flow have been obtained. (3) The high-order ENO schemes have been used to obtain time-accurate solutions of the Navier-Stokes equations to study the unsteady hypersonic shock-shock interference heating on a cylinder. The results show that the inherent unsteadiness has a strong effect on surface heating rates. The ENO schemes were found to work well for numerical simulations of transient hypersonic flow. DTIC

INCORPORATING RADIAL MIXING IN AXISYMMETRIC STREAMLINE CURVATURE THROUGH-FLOW ANALYSIS Final Technical Report, May 1992 - Sep. 1993
D. G. Grabowska and P. Kavanagh Sep. 1993 114 p
(Contract F49620-92-J-0226)
(AD-A277325; ISU-ERI-AMES-94-088; AFOSR-94-0079TR) Avail: CASI HC A06/MF A02

The development of governing equations for hub-to-tip streamline curvature solutions in turbomachinery passages and blade rows and incorporating viscous radial mixing is presented. Arbitrary passage geometries

and quasi-orthogonal description are accounted for. Fortran program coding is carried out for the special case of unbladed, axial-flow passages. Flow solutions are obtained by iteration based on fixed streamline patterns in the meridional plane followed by further iterations involving readjustment of the streamlines until overall convergence is obtained. Simple examples are presented to illustrate the solution technique. DTIC

A CRITICAL EVALUATION OF METHODS FOR IMPOSING SOLID-WALL BOUNDARY CONDITIONS IN INVISCID FLOW Final Report, Aug. - Sep. 1993
S. L. Keeling (Calspan Corp., Arnold AFS, TN.) Mar. 1994 37 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276959; AEDC-TR-93-23) Avail: CASI HC A03

This report presents a critical evaluation of widely used methods for imposing discrete solid-wall boundary conditions for the numerical computation of inviscid flows. Specifically, it shows that some of these methods are only provisionally correct. Also, an explanation is given for the success of others. In particular, the report shows that a method involving contravariant velocity components can generate distortions in computed flows. Because complex CFD calculations can be difficult to interpret, the claims made here are demonstrated with explicit solutions to simple model problems. This work emphasizes that subtle and erroneous effects can result from the use of apparently natural numerical methods. It also emphasizes the importance of developing simple tests for these computational methods to elucidate the possible consequences of their use. DTIC

Direct Simulation Monte Carlo (DSMC) is a simulation technique that uses particles to model fluids at low densities where continuum formulations break down. Monte Carlo rules are used to perform particle collisions and chemical reactions and a grid is used to locate nearby particles. We describe our implementation of a large-scale DSMC model on the thousand-processor nCUBE 2 and Intel Paragon machines. It includes body-fitted irregular grids and particle weighting to reduce the numbers of particles and grid cells that must be used. Our parallel methods for load-balancing and performing irregular communication on the distributed-memory machines are also discussed. The parallel machines have enabled us to run large simulations (10(exp 7) particles, 10(exp 4) grid cells, 10(exp 4) timesteps) at speeds up to 40 times faster (on our nCUBE 2) than on a Cray Y-MP processor. For illustration purposes, we include results from some of these large-scale simulations. DOE

HIGH-RESOLUTION NUMERICAL METHODS FOR COMPRESSIBLE MULTI-PHASE FLOW IN HIERARCHICAL POROUS MEDIA
J. A. Trangenstein 15 Mar. 1994 19 p
(Contract DE-FG05-92ER-25145)
(DE94-008261; DOE/ER-25145/T1) Avail: CASI HC A03/MF A01

This is the second year in the proposed three-year effort to develop high-resolution numerical methods for multi-phase flow in hierarchical porous media. The issues being addressed in this research are: Computational efficiency: field-scale simulation of enhanced oil recovery, whether for energy production or aquifer remediation, is typically highly under-resolved. This is because rock transport properties vary on many scales, and because current numerical methods have low resolution. Effective media properties: since porous media are formed through complex geologic processes, they involve significant uncertainty and scale-dependence. Given this uncertainty, knowledge of ensemble averages of flow in porous media can be preferable to knowledge of flow in specific realizations of the reservoir. However, current models of effective properties do not represent the observed behavior very well. Relative permeability models present a good example of this problem. In practice, these models seldom provide realistic representations of hysteresis, interfacial tension effects or three-phase flow; there are no models that represent well all three effects simultaneously. Wave propagation: since numerical methods must use the models for compoutations, oscillations could erroneously be attributed to numerical error rather than modeling difficulties. When wave propagation is well-understood by analysis, it can provide useful information about the expected behavior of the flows, and can assist in the development of high-resolution numerical methods. (NASA-CR-189648; NAS 1.26:189648) Avail: CASI HC A07/MF A02

Accurate numerical simulation of chemical vapor deposition (CVD) processes requires a general purpose computational fluid dynamics package combined with specialized capabilities for high temperature chemistry. In this report, we describe the implementation of these specialized capabilities in the spectral element code NEKTON. The thermal expansion of the gases involved is shown to be accurately approximated by the low Mach number perturbation expansion of the incompressible Navier-Stokes equations. The radiative heat transfer between multiple interacting radiating surfaces is shown to be tractable using the method of Gebhart. The disparate rates of reaction and diffusion in CVD processes are calculated via a point-implicit time integration scheme. We demonstrate the use above capabilities on prototypical CVD applications. COMPUTATIONAL MODELING OF CONVECTIVE HEAT TRANSFER TO LIQUID HYDROGEN COOLANT Ph.D. Thesis
Robert George Carlisle 1992 193 p
Avail: Univ. Microfilms Order No. DA9324896

A computational algorithm capable of modeling the flow down a coolant duct of a fluid whose thermophysical properties vary with temperature was created and applied. The algorithm is formulated separately in two and three dimensions. Both approaches use space marching of the parabolized Navier-Stokes equations combined with the iterative recalculation of the fluid properties and turbulent intensities. The two-dimensional algorithm also iteratively couples the temperature distribution in the fluid with the heat transfer distribution in the bounding material. The externally applied heat transfer modeled approximates anticipated conditions in the cowl lip of the National Aerospace Plane (NASP). The proposed cooling by liquid hydrogen of the large surface heat transfer caused by external shock/shock interaction was found to give temperatures in the leading edge material that were close to the thermal limits of prospective materials. It was found that the performance of the coolant (i.e. the ability to cool the structure below a specific temperature) was very sensitive to inlet conditions of the coolant fluid as well as to the mass flow rate. The spread of the heat transfer on passing through the bounding material was found to be considerable and significantly reduced the maximum temperature of the fluid. The results of the three dimensional modeling showed that the principal restraint on the ability of the duct flow to convect heat was the build up of heat in corner boundary layers. It was found that the addition of a vortex to the center of the cross-stream flow in the inlet was not effective in decreasing the maximum temperature of the heated fluid. Dirichlet boundary conditions (i.e. specified temperatures) calculated from the two-dimensional algorithm were applied to the three-dimensional algorithm and demonstrated similarity between the heat transfer coefficients calculated by both methods. Dissert. Abstr.

A CRITICAL EVALUATION OF THE REYNOLDS STRESS TURBULENCE CLOSURE FOR THE FLOW OF A TURBULENT FREE-STREAM OVER A TURBULENT BOUNDARY LAYER Ph.D. Thesis
John C. Mackinnon 1992 296 p
(ISBN-0-315-75792-2) Avail: Univ. Microfilms Order No. DANN75792

This thesis is concerned with the evaluation of a Reynolds stress turbulence closure (the Reynolds Stress Model) for the flow of a turbulent free-stream over the turbulent boundary layer on a flat plate. The interaction of turbulent flow with underlying boundary layer formed on a surface is a complex flow of interest in many practical engine problems. In order to

advance the ability of turbulence models to predict these flows, a clear understanding of the capability of existing models to account for important physical phenomena is necessary. The Reynolds Stress Model involves a set of partial differential equations representing conservation of turbulent stresses, where the stresses represent the transfer of momentum by turbulent fluctuations. In the present work, the thin shear layer form of the coupled governing equations were solved numerically using a finite volume method. Model predictions with the conventional Reynolds Stress Model (denoted CSM) have been compared to experimental data of local, mean and turbulent quantities gathered over a wide range of free-stream turbulence conditions. Based on comparison experimental data, it is found here that the CSM in general gives good predictions of local parameters, with the exception of the boundary layer thickness delta(sub 995). Experimentally observed effects of profile changes as a function of the free-stream turbulence intensity, I(sub infinity), and ratio of the free-stream length scale to boundary layer thickness, L(sub upsilon)(exp infinity) /delta, are also generally well predicted. It is identified that the CSM does not properly account for the effect of the wall on the external turbulence, resulting in the turbulent stress normal to the wall being attenuated at too great a distance. The conventionally applied gradient diffusion model of the third order correlations is also seen to under predict the experimental data when free-stream turbulence is present. New model formulations proposed to improve the treatment of these two aspects are developed and are shown to give better predictions. Dissert. Abstr.

ADDITIVE TURBULENT DECOMPOSITION OF THE INCOMPRESSIBLE AND COMPRESSIBLE NAVIER-STOKES EQUATIONS Final Report, 1991- 1993
J. M. McDonough, Y. Yang, and X. Zhong 1993 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-J-0113)
(AD-A277321; AFOSR-94-0076TR) Avail: CASI HC A03

Research results summarizing the past two years' efforts are presented. These include analysis of both the large and small-scale equations of additive turbulent decomposition (ATD) for the two dimensional incompressible Navier-Stokes equations. Both of these solution procedures are complete for Cartesian coordinates and check out is essentially finished for generalized coordinates. We discuss our method used to filter solutions to the large-scale equations, and the domain decomposition methods we are employing to recouple local small-scale solutions to produce global solutions on the small scale. We also present results obtained from our large-scale equations/chaotic map turbulence modeling approach for intermittent flow. DTIC

ANALYSIS AND COMPUTATION FOR VORTEX DYNAMICS AND RAREFIED GASES Final Technical Report, 1 Oct. 1989 - 30 Sep. 1993
Russel E. Caflisch 29 Nov. 1993 4 p
(Grant AF-AFOSR-0003-90)
(AD-A277415; AFOSR-94-0093TR) Avail: CASI HC A01/MF A01

Through support of this grant, a number of research projects on vortex dynamics and rarefied gas dynamics were completed. A few of the most outstanding results were the following: An analytic theory for singularity formation on the fluid interface in the Rayleigh-Taylor problem was developed and shown to agree with numerical results. Singular solutions were found by direct computation for Moore's approximation of the three dimensional Euler equations for axisymmetric flow with swirl. Generic form singularities for hyperbolic and elliptic equations were classified using catastrophe theory. The results were applied to shock waves, vortex sheets, and, in preliminary work, patterns in convective flows. DTIC

NOTES ON THE LANGEVIN MODEL FOR TURBULENT DIFFUSION OF MARKED PARTICLES
H. C. Rodean 26 Jan. 1994 122 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-007847; UCRL-ID-115869) Avail: Issuing Activity (Department of Energy (DOE))

Three models for scalar diffusion in turbulent flow (eddy diffusivity, random displacement, and on the Langevin equation) are briefly described. The model's random velocity increment based Fokker-Planck equation is introduced, and then, they are examined in more detail in the reverse order. The Fokker-Planck equation is the Eulerian equivalent of the Lagrangian Langevin equation, and the derivation is outlined. The procedure for obtaining the deterministic and stochastic components of the Langevin equation from Kolmogorov's 1941 inertial range theory and the Fokker-Planck equation is described. It is noted that a unique form of the Langevin equation can be determined for diffusion in one dimension but not in two or three. The Langevin equation for vertical diffusion in the non-Gaussian convective boundary layer is presented and successively simplified for Gaussian inhomogeneous turbulence and Gaussian homogeneous turbulence in turn. The Langevin equation for Gaussian inhomogeneous turbulence is mathematically transformed into the random displacement model. It is shown how the Fokker-Planck equation for the random displacement model is identical in form to the partial differential equation for the eddy diffusivity model. It is noted that the Langevin model is applicable in two cases in which the other two are not valid: (1) close in time and distance to the point of scalar release; and (2) the non-Gaussian convective boundary layer. The two- and three-dimensional cases are considered in Part 3. DOE

THERM3D: A BOUNDARY ELEMENT COMPUTER PROGRAM FOR TRANSIENT HEAT CONDUCTION PROBLEMS
M. S. Ingber (New Mexico Univ., Albuquerque.) Feb. 1994 25 p
(Contract DE-AC04-94AL-85000)
(DE94-008112; SAND-93-7072) Avail: CASI HC A03/MF A01

The computer code THERM3D implements the direct boundary element method (BEM) to solve transient heat conduction problems in arbitrary three dimensional domains. This particular implementation of the BEM avoids performing time consuming domain integrations by approximating a 'generalized forcing function' in the interior of the domain with the use of radial basis functions. An approximate particular solution is then constructed, and the original problem is transformed into a sequence of Laplace problems. The code is capable of handling a large variety of boundary conditions including isothermal, specified flux, convection, radiation, and combined convection and radiation conditions. The computer code is benchmarked by comparisons with analytic and finite element results. DOE

A STUDY OF NEAR-SURFACE AND UNDERWATER EXPLOSIONS BY COMPUTER SIMULATIONS
M. Kamegai and J. W. White Feb. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-009038; UCRL-ID-116360) Avail: CASI HC A03

Computer simulations were made for 13 near-surface and underwater explosions from generic 1-kt and 10-kt sources. The objective is to calculate energy coupling to the water and to understand conditions that drive signals into the ocean sound channel. The simulation used the CALE computer program which was previously validated using the WIGWAM test data. A 1-kt underwater explosion achieves its maximum coupling at about 20 m DOB, and the downward kinetic energy is less than 15% of the yield. As the source is lifted above the surface the coupling efficiency decreases dramatically. A comparison of underwater explosion simulations for the two different yields confirmed that hydrodynamic dimensions scale by the cube root of the yield. DOE

Avail: CASI HC A16/MF A03

The effects of mechanical protrusions on the jet mixing characteristics of rectangular nozzles for heated and unheated subsonic and supersonic jet plumes were studied. The characteristics of a rectangular nozzle of aspect ratio 4 without the mechanical protrusions were first investigated. Intrusive probes were used to make the flow measurements. Possible

errors introduced by intrusive probes in making shear flow measurements were also examined. Several scaled sizes of mechanical tabs were then tested, configured around the perimeter of the rectangular jet. Both the number and the location of the tabs were varied. From this, the best configuration was selected. The conclusions derived were: (1) intrusive probes can produce significant errors in the measurements of the velocity of jets if they are large in diameter and penetrate beyond the jet center; (2) rectangular jets without tabs, compared to circular jets of the same exit area, provide faster jet mixing; and (3) further mixing enhancement is possible by using mechanical tabs. COMPUTATION OF THREE-DIMENSIONAL COMPRESSIBLE BOUNDARY LAYERS TO FOURTH-ORDER ACCURACY ON WINGS AND FUSELAGES Final Report
Venkit Iyer Jan. 1990 275 p
(Contract NAS1-18585; RTOP 505-60-31-05)
(NASA-CR-4269; NAS 1.26:4269) Avail: CASI HC A12/MF A03

A solution method, fourth-order accurate in the body-normal direction and second-order accurate in the stream surface directions, to solve the compressible 3-D boundary layer equations is presented. The transformation used, the discretization details, and the solution procedure are described. Ten validation cases of varying complexity are presented and results of calculation given. The results range from subsonic flow to supersonic flow and involve 2-D or 3-D geometries. Applications to laminar flow past wing and fuselage-type bodies are discussed. An interface procedure is used to solve the surface Euler equations with the inviscid flow pressure field as the input to assure accurate boundary conditions at the boundary layer edge. Complete details of the computer program used and information necessary to run each of the test cases are given in the Appendix.

ENHANCEMENT OF MIXING IN A RECTANGULAR JET BY MECHANICAL TABS
W. H. Brown and K. K. Ahuja Apr. 1990 86 p
(Grant NAG3-1062; RTOP 505-62-00)
(NASA-CR-185207; A-8402; NAS 1.26:185207) Avail: CASI HC A05/MF A01

This effort was conducted to obtain additional test data/configurations required to better understand the effects of tab length and width on jet mixing enhancement for a rectangular nozzle. The configurations tested were a six-tab configuration defined by NASA, a full-height tab configuration, and two-tab configurations with selected tab lengths and widths. Additional test data were also required for all candidate configurations to better interpret the data. Test data from this effect are presented. On the basis of these data, the following general observations were noted: The six-tab rectangular nozzle configuration provided a lower peak velocity than either the two-tab or four-tab configuration; and the rectangular nozzle with a full-height tab had about the same peak velocity as the two-tab configuration; however, the full-height tab configuration had a somewhat lower centerline velocity. INCREMENTAL TRIANGULATION BY WAY OF EDGE SWAPPING AND LOCAL OPTIMIZATION
N. Lyn Wiltberger Jan. 1994 43 p
(RTOP 505-59-50)
(NASA-TM-103979; A-92196; NAS 1.15:103979) Avail: CASI HC A03/MF A01

This document is intended to serve as an installation, usage, and basic theory guide for the two dimensional triangulation software 'HARLEY' written for the Silicon Graphics IRIS workstation. This code consists of an incremental triangulation algorithm based on point insertion and local edge swapping. Using this basic strategy, several types of triangulations can be produced depending on user selected options. For example, local edge swapping criteria can be chosen which minimizes the maximum interior angle (a MinMax triangulation) or which maximizes the minimum interior angle (a MaxMin or Delaunay triangulation). It should be noted that the MinMax triangulation is generally only locally optical (not globally optimal) in this measure. The MaxMin triangulation, however, is both locally and globally optical. In addition, Steiner triangulations can be constructed by inserting new sites at triangle circumcenters followed by edge swapping based on the MaxMin criteria. Incremental insertion of sites also provides flexibility in choosing cell refinement criteria. A dynamic heap structure has been implemented in the code so that once a refinement measure is specified (i.e., maximum aspect ratio or some measure of a solution gradient for the solution adaptive grid generation) the cell with the largest value of this measure is continually removed from the top of the heap and refined. The heap refinement strategy allows the user to specify either the number of cells desired or refine the mesh until all cell refinement measures satisfy a user specified tolerance level. Since the dynamic heap structure is constantly updated, the algorithm always refines the particular cell in the mesh with the largest refinement criteria value. The code allows the user to: triangulate a cloud of prespecified points (sites), triangulate a set of prespecified interior points constrained by prespecified boundary curve(s), Steiner triangulate the interior/exterior of prespecified boundary curve(s), refine existing triangulations based on solution error measures, and partition meshes based on the Cuthill-McKee, spectral, and coordinate bisection strategies. MODIFICATION OF THE MML TURBULENCE MODEL FOR ADVERSE PRESSURE GRADIENT FLOWS M.S. Thesis - Akron Univ., 1993
Julianne M. Conley Apr. 1994 96 p
(RTOP 505-62-52)
(NASA-TM-106544; E-8690; NAS 1.15:106544) Avail: CASI HC A05/MF A01

Computational fluid dynamics is being used increasingly to predict flows for aerospace propulsion applications, yet there is still a need for an easy to use, computationally inexpensive turbulence model capable of accurately predicting a wide range of turbulent flows. The Baldwin-Lomax model is the most widely used algebraic model, even though it has known difficulties calculating flows with strong adverse pressure gradients and large regions of separation. The modified mixing length model (MML) was developed specifically to handle the separation which occurs on airfoils and has given significantly better results than the Baldwin-Lomax model. The success of these calculations warrants further evaluation and development of MML. The objective of this work was to evaluate the performance of MML for zero and adverse pressure gradient flows, and modify it as needed. The Proteus Navier-Stokes code was used for this study and all results were compared with experimental data and with calculations made using the Baldwin-Lomax algebraic model, which is currently available in Proteus. The MML model was first evaluated for zero pressure gradient flow over a flat plate, then modified to produce the proper boundary layer growth. Additional modifications, based on experimental data for three adverse pressure gradient flows, were also implemented. The adapted model, called MMLPG (modified mixing length model for pressure gradient flows), was then evaluated for a typical propulsion flow problem, flow through a transonic diffuser. Three cases

were examined: flow with no shock, a weak shock and a strong shock. The results of these calculations indicate that the objectives of this study have been met. Overall, MMLPG is capable of accurately predicting the adverse pressure gradient flows examined in this study, giving generally better agreement with experimental data than the Baldwin-Lomax model. MAGNETOHYDRODYNAMIC BOUNDARY LAYER CONTROL SYSTEM Patent
James C. Meng, inventor (to Navy) 28 Dec. 1993 6 p Filed 11 Feb. 1993
(AD-D016120; US-Patent-5,273,465; US-Patent-Appl-SN-016325; US-Patent-Class-440-6) Avail: US Patent and Trademark Office

An active boundary layer control system for marine vehicles is disclosed. The boundary layer control system comprises a plurality of magnets and seawater electrodes placed in circumferential rows around the beam of the hull. The magnets and electrodes are positioned so that a Lorentz force generated by the interacting magnetic and electric fields will drive the boundary layer flow in an axial direction toward the aft end of the bull. The boundary control system reduces turbulence and may relaminarize boundary layer flow, thereby reducing radiated noise. DTIC

IMPLEMENTATION OF A VIBRATIONALLY LINKED CHEMICAL REACTION MODEL FOR DSMC
A. B. Carlson and Graeme A. Bird Apr. 1994 11 p
(RTOP 232-01-04-04)
(NASA-TM-109109; NAS 1.15:109109) Avail: CASI HC A03/MF A01

A new procedure closely linking dissociation and exchange reactions in air to the vibrational levels of the diatomic molecules has been implemented in both one- and two-dimensional versions of Direct Simulation Monte Carlo (DSMC) programs. The previous modeling of chemical reactions with DSMC was based on the continuum reaction rates for the various possible reactions. The new method is more closely related to the actual physics of dissociation and is more appropriate to the particle nature of DSMC. Two cases are presented: the relaxation to equilibrium of undissociated air initially at 10,000 K, and the axisymmetric calculation of shuttle forebody heating during reentry at 92.35 km and 7500 m/s. Although reaction rates are not used in determining the dissociations or exchange reactions, the new method produces rates which agree astonishingly well with the published rates derived from experiment. The results for gas properties and surface properties also agree well with the results produced by earlier DSMC models, equilibrium air calculations, and experiment. Author

RENORMALIZATION GROUP THEORY OF BOLGIANO SCALING IN BOUSSINESQ TURBULENCE
Robert Rubinstein May 1994 19 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106602; ICOMP-94-8; E-8877; NAS 1.15:106602; CMOTT-94-2) Avail: CASI HC A03/MF A01

Bolgiano scaling in Boussinesq turbulence is analyzed using the Yakhot-Orszag renormalization group. For this purpose, an isotropic model is introduced. Scaling exponents are calculated by forcing the temperature equation so that the temperature variance flux is constant in the inertial range. Universal amplitudes associated with the scaling laws are computed by expanding about a logarithmic theory. Connections between this formalism and the direct interaction approximation are discussed. It is suggested that the Yakhot-Orszag theory yields a lowest order approximate solution of a regularized direct interaction approximation which can be corrected by a simple iterative procedure. THE STRUCTURE OF HIGH REYNOLDS NUMBER TURBULENT BOUNDARY LAYERS, PART A Final Technical Report, Dec. 1989 - Dec. 1993
James G. Brasseur 15 Feb. 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0113-90)
(AD-A278392; AFOSR-94-0207TR) Avail: CASI HC A03

We provide a summary of our accomplishments under a three-year 'mini URI' program in collaboration with researchers at Yale and Princeton universities. Whereas the central theme of the program is high Reynolds number wall-bounded turbulence, studies at Penn State included analysis of fundamental issues of scale interactions in high Reynolds number turbulence dynamics, the use of the wavelet decomposition and generalized filtering techniques in describing the relationship between the Fourier-spectral description of scale and the physical-space description of structure, direct numerical simulation of passive scalar sources in low Reynolds number turbulent boundary layers and analysis of scalar evolution in relationship to laboratory data, the relationship between homogeneous turbulent shear flow and the inertial sublayer in high Reynolds number turbulent boundary layers, and the development and application of sophisticated data analysis techniques which intimately combine graphical and quantitative analysis within a fully interactive 'analytical environment.' A brief summary of the accomplishments in each area of development is presented. DTIC

The first fully-resolved, nonintrusive, experimental measurements of the spatio-temporal structure and dynamics of the full nine-component velocity gradient tensor field gradient-u(x,t) in a turbulent flow are here obtained by applying the scalar imaging velocimetry technique to laboratory turbulent flow scalar field data. A variational method implementing this concept is described in which weighted residuals of the conserved scalar transport equation, the continuity condition, and a derivative smoothness condition are minimized over the space of velocity fields. The technique is applied to direct numerical simulation (DNS) data for the limiting case of turbulent mixing of a Sc = 1 passive scalar field. The spatial velocity fields u(x,t) obtained correlate well with the exact DNS results, as do statistics of the velocity and velocity gradient fields. The method is then applied to fully resolved four dimensional Sc much greater than 1 scalar field imaging measurements from a laboratory turbulent flow. Results give the first fully resolved data for the time-varying (u, v, w) vector velocity

component fields simultaneously everywhere on a regular three dimensional spatial grid in a turbulent flow. Direct differentiation of these fields yields the spatial structure in the full velocity gradient tensor field components. From these, the vector vorticity field wi(x,t) and tensor strain rate field epsilon-ij(x,t) are extracted, as are the kinetic energy density field k(x;t), the kinetic energy dissipation rate field phi(x;t), and the enstrophy field W(x;t). Finally, extraction of the time evolution in these fields is demonstrated by applying this scalar imaging velocimetry method to perform the inversion for the velocity field at several sequential time steps. BACKWARD-FACING STEP MEASUREMENTS AT LOW REYNOLDS NUMBER, Re(SUB h)=5000

Srba Jovic (Eloret Corp., Palo Alto, CA.) and David M. Driver Feb. 1994 26 p Original contains color illustrations

(RTOP 505-59-50)

(NASA-TM-108807; A-94043; NAS 1.15:108807) Avail: CASI HC A03/MF A01; 2 functional color pages

An experimental study of the flow over a backward-facing step at low Reynolds number was performed for the purpose of validating a direct numerical simulation (DNS) which was performed by the Stanford/NASA Center for Turbulence Research. Previous experimental data on back step flows were conducted at Reynolds numbers and/or expansion ratios which were significantly different from that of the DNS. The geometry of the experiment and the simulation were duplicated precisely, in an effort to perform a rigorous validation of the DNS. The Reynolds number used in the DNS was Re(sub h)=5100 based on step height, h. This was the maximum possible Reynolds number that could be economically simulated. The boundary layer thickness, d, was approximately 1.0 h in the simulation and the expansion ratio was 1.2. The Reynolds number based on the momentum thickness, Re(sub theta), upstream of the step was 610. All of these parameters were matched experimentally. Experimental results are presented in the form of tables, graphs and a floppy disk (for easy access to the data). An LDV instrument was used to measure mean velocity components and three Reynolds stresses components. In addition, surface pressure and skin friction coefficients were measured. LDV measurements were acquired in a measuring domain which included the recirculating flow region. Author

PARTICLE IDENTIFICATION IN A SEGMENTED CALORIMETER (NUMASS TEST DATA, SEPTEMBER 1991)

Q.-P. Zhang 15 Sep. 1993 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(USIP-93-08; ETN-94-95940) Avail: Issuing Activity (European Space Agency (ESA))

The ZEUS T60 uranium/scintillator calorimeter was the main detector in the NUMASS test run, which took place at the Super Proton Synchrotron (SPS) facility. Additional scintillators were embedded in the calorimeter for high precision measurement of the arrival time for hadronic particle. High energy pion beams were used to test the performance of the calorimeter and to measure the arrival time distribution for hadrons. The segmentation of the calorimeter makes it possible to measure different shower profiles in the detector which is then used to identify and discriminate against contamination in the pion beam of electrons and muons. The particle identification is described. ESA

(ISSN 0751-1345)

(TELECOM-93-D-007; ETN-94-95888) Avail: CASI HC A03

The possibility of tracking roads in aerial images in order to achieve an automatic extraction of the road network is studied. An analogy with the classical problem of moving targets tracking is proposed and an algorithm for roads tracking based on Kalman filtering is developed. For this, as observation space, both the image of the contours and the image of the gradient direction extracted from the original image with a classical Canny-Deriche detector are used. The modelization and the initialization of the parameters is possible because hypothesis on the roads characteristics was made. To improve this tracking tool, the radiometric information was used in a test a posteriori and two criteria to detect bad tracks were defined. It is shown how it is possible to take advantage of data extracted from a map of the region under study and previously registered. More precisely, information about crossroads (position, topology) is used so that the algorithm becomes robust when going through such areas. This also enables an automatic initialization of the tracking process and leads, with a recursive use of the program, to the possibility of recovering on the image the road network previously extracted from the map. CONCEPT, CONSTRUCTION AND TESTING OF A HIGH RESOLUTION QCLAM ELECTRON SPECTROMETER WITH LARGE SOLID ANGLE AND HIGH IMPULSE ACCEPTANCE FOR THE ELECTRON ACCELERATOR S-DALINAC Ph.D. Thesis [KONZEPTION, AUFBAU UND ERPROBUNG EINES HOCHAUFLOESENDEN QCLAM-ELEKTRONENSPEKTROMETERS MIT GROSSEM RAUMWINKEL UND HOHER IMPULSAKZEPTANZ AM ELEKTRONENBESCHLEUNIGER S-DALINAC]

Martin Knirsch 1991 91 p In GERMAN

(ETN-94-95755) Avail: CASI HC A05/MF A01

A magnetic QCLAM electron spectrometer was designed, constructed, and tested for the electron accelerator S-DALINAC. It consists of a

quadrupole magnet and a dipole magnet. The solid angle is 35 mst, and energies up to 200 MeV with an impulse acceptance of +/- 10% scattering angle can be detected. The fields of quadrupole and dipole magnets were measured with Hall probes and agree within 1% of the design valves. The imaging characteristics of the spectrometer were tested using elastically scattered electrons. A method to determine the electron trajectories in the target plane was developed. The scattered electrons are measured with a detector system with three multi wire drift chambers. A shielding system was constructed to suppress the background in the detector system due to gamma rays and neutrons. ESA

Photoelectron diffraction and photoelectron holography, a newly developed variant, can provide a rich range of information concerning surface structure. These methods are sensitive to atomic type, chemical state, and spin state. The theoretical prediction of diffraction patterns is also well developed at both the single scattering and multiple scattering levels, and quantitative fits of experiment to theory can lead to structures with accuracies in the +/-0.03 A range. Direct structural information can also be derived from forward scattering in scanned-angle measurements at higher energies, path length differences contained in scanned-energy data at lower energies, and holographic inversions of data sets spanning some region in angle and energy space. Diffraction can also affect average photoelectron emission depths. Circular dichroism in core-level emission can be fruitfully interpreted in terms of photoelectron diffraction theory, as can measurements with spin-resolved core-spectra, and studies of surface magnetic structures and phase transitions should be possible with these methods. Synchrotron radiation is a key element of fully utilizing these techniques. DOE

Millimeter wave holographic imaging systems capable of imaging through clothing to detect contraband, metal, plastic, or ceramic weapons may provided a practical solution to personnel inspection needs in mass transportation centers. Traditional inspection systems, such as metal detectors and x-ray imaging systems, have limitations for the detection of concealed weapons. Metal detectors are limited because they cannot detect plastic weapons and x-ray imaging systems are limited in use due to radiological health considerations. A prototype millimeter wave holographic surveillance system has been developed and demonstrated at the Pacific Northwest Laboratory (PNL). The prototype millimeter wave holographic surveillance system developed at PNL consists of a sequentially switched 2 (times) 64 element array coupled to a 35 GHz bi-static transceiver. The sequentially switched array of antennas can be used to obtain the holographic data at high speed by electronically sequencing the antennas along one dimension and performing a mechanical scan along the other dimension. A one-dimensional mechanical scan be be performed in about one second. The prototype system scans an aperture of 0.75 by 2.05. This system has been demonstrated and images have been obtained on volunteers at Sea-Tac International airport in Seattle, Washington. DOE

A PARAPERSPECTIVE FACTORIZATION METHOD FOR SHAPE AND MOTION RECOVERY
Conrad J. Poelman and Takeo Kanade 11 Dec. 1993 36 p
(Contract F33615-90-C-1465; ARPA Order 7597)
(AD-A276513; CMU-CS-93-219) Avail: CASI HC A03/MF A01

The factorization method, first developed by Tomasi and Kanade, recovers both the shape of an object and its motion from a sequence of images, using many images and tracking many feature points to obtain highly redundant feature position information. The method robustly processes the feature trajectory information using singular value decomposition (SVD), taking advantage of the linear algebraic properties of orthographic projection. However, an orthographic formulation limits the range of motions the method can accommodate. Paraperspective projection, first introduced by Ohta, is a projection model that closely approximates perspective projection by modeling several effects not modeled under orthographic projection, while retaining linear algebraic properties. Our paraperspective factorization method can be applied to a much wider range of motion scenarios, such as image sequences containing significant translational motion toward the camera or across the image. The method also can accommodate missing or uncertain tracking data, which occurs when feature points are occluded or leave the field of view. We present the results of several experiments which illustrate the method's performance in a wide range of situations, including an aerial image sequence of terrain taken from a low-altitude air plane. (DA Proj. RM-3-3-T-24)
(AD-A277004; NAWCTSD-TR-93-021) Avail: CASI HC A03/MF A01

In order to obtain night vision device imagery, a portable lightweight night vision camcorder system has been designed. This system has the capability to record night vision imagery in confined quarters (e.g., cockpits) and other remote sites under various environmental conditions. The system is composed of a commercial third generation night vision monocular, a special optical coupler, and a consumer camcorder. Engineering drawings for the optical coupler are included as an appendix. Laboratory experiments were performed to determine the night vision camcorder system imaging characteristics. The results of these experiments indicate that the limiting resolution of recorded night vision video is about 30% to 40% of the limiting resolution of the third generation monocular, depending upon the type of video filming method used. ULTRA WIDE BAND RADAR HOLOGRAPHIC IMAGING OF SUBSURFACE TARGETS

H. D. Collins and R. P. Gribble Aug. 1993 8 p Presented at the 20th Annual Review of Progress in Quantitative Nondestructive Evaluation (NDE), Brunswick, ME, 1-6 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC06-76RL-01830)
(DE94-004271; PNL-SA-22301; CONF-9308167-6) Avail: CASI HC A02

This report discusses ultra wide band (i.e., 60 ps impulse) radar holography which is a unique technique for imaging subsurface targets with extremely high lateral and depth resolution. The large frequency bandwidth, typically 100%, provides excellent depth resolution and the synthetic aperture optimum lateral resolution of one-half wavelength at the center pulse frequency. Radar impulse holography can simply be described as a multi-frequency detection and imaging technique where the target's broadband time waveform signals are recorded over a defined aperture; decomposed into their discrete frequency components as single frequency holograms, and reconstructed into a composite image. Computer generated holograms are constructed for each frequency component in the 3-dB pulse bandwidth and plane wave angular spectra computed to provide unique detection analysis with respect to target identification, etc. The hologram at each frequency component in the pulse can be thought of as a diffraction lens for each reflecting point on the target. A complex target consists, of a multitude of points, and the recorded hologram becomes the superposition of these individual diffraction lens. It is a unique diffraction pattern capable of defining the target's image and scattering characteristics in the near- and far-field. DOE

EG&G/EM has developed an oscilloscope with a -3 dB bandwidth greater than 10 GHz. Its rolloff characteristics are such that single-transient data greater than 20 GHz may be captured. A demountable CCD camera records the oscilloscope trace and is provided with PC-compatible capture and data processing software. The capabilities of the oscilloscope, camera, and its processing software are described and examples of the system's performance is shown. DOE

PERFORMANCE OF AN ION TRAP INDUCTIVELY COUPLED PLASMA MASS SPECTROMETER

D. W. Koppenaal, C. J. Barinaga, and M. R. Smith Jan. 1994 3 p Presented at the 1994 Winter Conference on Plasma Spectrochemistry, San Diego, CA, 10-15 Jan. 1994
(Contract DE-AC06-76RL-01830)
(DE94-007470; PNL-SA-22700; CONF-940167-1) Avail: CASI HC A01/MF A01

A prototype instrument comprising an inductively coupled plasma ion source and an ion trap mass spectrometer detector has been constructed, operated, and tested for improved elemental and isotopic analysis. The rationale for this work follows from recent achievements in the ion trap mass spectrometry (ITMS) field and the realization that coupling this mass spectrometer with the powerful ICP ion source may provide distinct analytical advantages. Potential benefits could include increased sensitivity (resulting from analyte ion isolation and subsequent detection against a dark background), atomic isobar resolution (extremely high ITMS resolution has been demonstrated), destruction of polyatomic interferences (via collisional dissociation or in-trap chemistry), and size reduction of instrumentation. STABILIZED ALUMINA/ETHANOL COLLOIDAL DISPERSION FOR SEEDING HIGH TEMPERATURE AIR FLOWS

Judith H. Wernet and Mark P. Wernet May 1994 10 p Proposed for presentation at the Symposium on Laser Anemometry: Advances and Applications, Lake Tahoe, NV, 19-23 Jun. 1994; sponsored by ASME
(RTOP 505-62-50)
(NASA-TM-106591; E-8858; NAS 1.15:106591) Avail: CASI HC A02/MF A01

Seeding air flows with particles to enable measurements of gas velocities via laser anemometry and/or particle image velocimetry techniques can be quite exasperating. The seeding requirements are compounded when high temperature environments are encountered and special care must be used in selecting a refractory seed material. The pH stabilization techniques commonly employed in ceramic processing are used to obtain stable dispersions for generating aerosols of refractory seed material. By adding submicron alumina particles to a preadjusted pH solution of ethanol, a stable dispersion is obtained which when atomized produces a high quality aerosol. Commercial grade alumina powder is used with a moderate size distribution. The technique is not limited to alumina/ethanol and is also demonstrated with an alumina/H2O system. Other ceramic powders in various polar solvents could also be used once the point of zero charge (pH(sub pzc)) of the powder in the solvent has been determined. Author

TRANSIENT RADIATION-INDUCED ABSORPTION IN THE MATERIALS FOR A GSGG LASER
P. J. Brannon Nov. 1993 25 p
(Contract DE-AC04-94AL-85000)
(DE94-005316; SAND-93-2417) Avail: CASI HC A03/MF A01

Materials used in the optical elements of a 1,061 m GSGG (gadolinium scandium gallium garnet) laser have been tested for transient radiation-induced absorption. The transient radiation-induced absorption in KK1, Schott S7005 and S7010, and M382 glasses have been determined for discrete wavelengths in the range 440-750 nm. Also, the transient radiation-induced absorption in 'pure' and MgO doped LiNbO3 has been measured at 1,061 nm. Mathematical expressions composed of exponentials are fitted to the data. DOE

(DE94-005873; DOE/ER-13421/10) Avail: CASI HC A03/MF A01

The objective of this program was to make quantitative measurements of the effects of higher-order phase/frequency correlations in a laser beam on nonlinear optical absorption processes in atoms. The success of this program was due in large part to a unique experimental capability for modulating the extracavity beam of a stabilized (approximately less than 200 kHz) continuous-wave laser with statistically-well-characterized stochastic phase (or frequency) fluctuations, in order to synthesize laser bandwidths to approximately 20 MHz (depending on noise amplitude), with profiles variable between Gaussian and Lorentzian (depending on noise bandwidth). Laser driven processes investigated included the following: (1) the optical Autler-Towns effect in the 3S(sub 1/2) (F = 2, M(sub F) = 2) yields 3P(sub 3/2) (F = 3, M(sub F) = 3) two-level Na resonance, using a weak probe to the 4D(sub 5/2) level; (2) the variance and spectra of fluorescence intensity fluctuations in the two-level Na resonance; (3) the Hanle effect in the (sup 1)S(sub 0) - (sup 3)P(sub 1), transition at lambda = 555.6 nm in Yb-174; (4) absorption (and gain) of a weak probe, when the probe is a time-delayed replica of the resonant (with the two-level Na transition) pump laser; and (5) four-wave-mixing in a phase-conjugate geometry, in a sodium cell, and, finally, in a diffuse atomic sodium beam. The experimental results from these several studies have provided important confirmation of advanced theoretical methods. DOE

THE ROLE OF DEFECTS IN LASER DAMAGE OF MULTILAYER COATINGS
M. R. Kozlowski and R. Chow 21 Dec. 1993 9 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-006731; UCRL-JC-113493; CONF-931054-7) Avail: CASI HC A02/MF A01

Laser induced damage to optical coatings is generally a localized phenomenon associated with coating defects. The most common of the defect types are the well-known nodule defect. This paper reviews the use of experiments and modeling to understand the formation of these defects and their interaction with laser light. Of particular interest are efforts to identify which defects are most susceptible to laser damage. Also discussed are possible methods for stabilizing these defects (laser conditioning) or preventing their initiation (source stabilization, spatter particle trapping). DOE

During the past three years we have made substantial progress toward the goal of a fiber coupled, diode laser pumped 100W cw Nd:YAG minislab laser. We have diode pumped a 1W ring cavity laser and have operated it in a single frequency. We have diode pumped a testbed minislab Nd:YAG laser using fiber coupled diode laser bars and generated 5W of cw, TEMoo mode output power. We have designed and are implementing a 50W cw minislab Nd:YAG laser to be pumped by 25 diode laser bars coupled through optical fibers. We plan, in the second phase of this program, to achieve the 100W cw output power level in a minislab Nd:YAG laser approach proposed as the goal of this research program. In addition, we have demonstrated single frequency control of a high power Nd:YAG laser oscillator by injection locking; have frequency stabilized Nd:YAG oscillators by locking to high finesse Fabry Perot resonators; have absolutely stabilized Nd:YAG to one part in 10 to the -13th power by locking to iodine; have frequency converted Nd:YAG by second harmonic generation to 11.2W of cw TEMoo mode green output; have demonstrated the first cw 2 microns OPO in lithium niobate; and have demonstrated the first cw singly resonant OPO with 2W of output in a single frequency in KTP. We are investigating quasi-phase-matched diffusion-bonded (QPM-DB) GaAs for nonlinear infrared applications. We have fabricated diffusion-bonded stacks of up to nine layers, which we have used to demonstrate quasi-phase-matched second-harmonic generation pumped by 10.6-micrometers CO2 laser output. Preliminary optical damage tests of diffusion-bonded-stacked GaAs indicate a power handling capability in excess of other currently available nonlinear infrared materials. Numerical calculations modeling nonlinear frequency conversion and projectioned device performance are included in this report. DTIC

AUTOMATIC RESONATOR ALIGNMENT AND POWER STABILIZATION OF HIGH POWER C02 LASERS Ph.D. Thesis
Dale Richard Akitt 1992 221 p
(ISBN-0-315-77217-4) Avail: Univ. Microfilms Order No. DANN77217

The high power carbon dioxide laser has become a very important tool in the area of industrial materials processing. This is due primarily to the enormous optical intensities which the device can attain. Unfortunately, it has proved increasingly difficult to construct machines capable of maintaining a consistently uniform output beam at elevated power levels, for extended periods. These difficulties are often attributed to thermal

distortion of the resonator optics. Because of this fact, researchers have invested considerable effort in the construction of water cooled, thermally stable optical benches, upon which to mount the resonator components. This approach is very expensive, and has provided only a partial solution to the problem. A different approach, and the subject of this thesis, is to construct a feedback control system which actively repositions the optical elements, so as to maintain optimum resonator alignment. Preliminary experiments demonstrated that this concept was indeed feasible. In this first study, a circular array of small thermistors was utilized as the feedback element. Indicators of mode uniformity in the vertical and horizontal directions were extracted from the array using electronic techniques. A relay type controller monitored these error measures and subsequently activated a pair of motor-micrometers fitted to one of the primary resonator mirrors. Although this thermistor-based system demonstrated the viability of the concept, the sensor array's slow response limited its performance. Subsequent experiments utilizing high speed pyroelectric detectors in place of the thermistors solved the problem. The next series of experiments was dedicated to finding a method of simultaneously aligning both primary resonator mirrors. This was accomplished by configuring the sensor array to monitor not only beam uniformity, but also beam position. A new controller was then developed which adjusted one mirror based on the position of the output beam, while the second mirror was employed to continuously maintain mode uniformity. This 'two mirror' control system has demonstrated the ability to consistently maintain optimum resonator alignment for indefinite periods, at arbitrary power levels up to 10 kW. Dissert. Abstr.

FALCON is a high power, steady state, nuclear reactor-pumped laser (RPL) concept that is being developed by the Department of Energy. The FALCON program has experimentally demonstrated reactor-pumped lasing in various mixtures of xenon, argon, neon, and helium at wavelengths of 585, 703, 725, 1271, 1733, 1792, 2032, 2630, 2650, and 3370 nm with intrinsic efficiency as high as 2.5 percent. The major strengths of a reactor-pumped laser are continuous high-power operation, modular construction, self-contained power, compact size, and a variety of wavelengths (from visible to infrared). These characteristics suggest numerous applications not easily accessible to other laser types. A ground-based RPL could beam its power to space for such activities as illuminating geosynchronous communication satellites in the earth's shadow to extend their lives, beaming power to orbital transfer vehicles, removing space debris, and providing power to a lunar base during the long lunar night. The compact size and self-contained power also makes an RPL very suitable for ship basing so that power-beaming activities could be situated around the globe. The continuous high power of an RPL opens many potential manufacturing applications such as deep-penetration welding and cutting of thick structures, wide-area hardening of metal surfaces by heat treatment or cladding application, wide-area vapor deposition of ceramics onto metal surfaces, production of submicron sized particles for manufacturing of ceramics, wide-area deposition of diamond-like coatings, and three dimensional ceramic lithography. TRANSVERSE MODE ANALYSIS OF HOLE-COUPLED FREE-ELECTRON LASERS Ph.D. Thesis
Bart Faatz 1992 122 p Sponsored by Netherlands Organization for Scientific Research, and Euratom
(ETN-94-96019) Avail: CASI HC A06/MF A02

The influence of the aperture on the Free Electron Laser (FEL) intracavity mode structure was investigated. Both the influence of the electron beam and of the resonator geometry are investigated, with emphasis on the latter. The basic equations describing the interaction between the electrons and the combined undulator and radiation fields are derived. A Three Dimensional Axisymmetric (TDA) code was extended to allow multiple passes of the light wave in a resonator geometry including apertures in one or both mirrors. To determine the influence of the aperture on the mode structure, simulations were performed in a resonator including the gain medium but without aperture. The same resonator generators were investigated including an aperture in the upstream mirror. The FELIX (FEL for Infrared eXperiments project) geometry and beam parameters are used to simulate the first experiments with FELIX. ESA

FREE ELECTRONS AS A VERSATILE SOURCE OF COHERENT RADIATION Ph.D. Thesis
Rene Johan Bakker 1993 119 p Sponsored by Netherlands Organization for Scientific Research Prepared in cooperation with FOM-Inst. voor Plasmafysica
(ETN-94-96011) Avail: CASI HC A06/MF A02

The construction of the Free Electron Laser (FEL) for Infrared experiments (FELIX) user facility is addressed. The objectives for this project were to construct an FEL, capable of producing high power short pulse radiation, continuously and rapidly tunable from 8 to 80 micrometers. Additionally, an optional phase locking scheme was designed in order to obtain narrow bandwidth radiation, that is, radiation with a bandwidth equal to a single longitudinal cavity mode. At present, FELIX covers the wavelength range from 6.5 to 110 micrometers. It is argued that the design objectives can be obtained with a high quality (for example, low energy spread) electron beam consisting of high current short pulse electron bunches. With FELIX, the electron beam consists of 5 ps long electron bunches (full width) with a current up to 60 A. The beam energy ranges from 15 to 45 MeV. The performance of the system producing this electron beam is discussed. It consists of a thermionic gun, a prebuncher, a buncher, and two standard commercial linac sections. The gun is modulated at 1 GHz in order to obtain bunches with a duration of 280 ps. After compression to 35 ps by the prebuncher, the bunches are accelerated to 3.8 MeV in the buncher and simultaneously compressed to 6 ps. Further compression is obtained in the first linac. The performance of the system is more than adequate, for example a root mean square energy spread of 0.3 behind the RF linac. The selection of narrow band radiation, which is useful for high resolution spectroscopy applications from the output of FELIX, is presented. ESA

TIME EVOLUTION AND FILAMENTATION OF KrF(STAR) LASER GAS DISCHARGES Ph.D. Thesis [ZEITLICHE ENTWICKLUNG UND FILAMENTIERUNG VON KRF(STAR)-LASERGASENTLADUNGEN]
Thomas Mueller 1992 150 p In GERMAN Sponsored by BMFT
(ETN-94-95758) Avail: CASI HC A07/MF A02

Independent KrF(star) high pressure laser gas discharges were theoretically and experimentally investigated. An analytic discharge model was developed for the homogeneous phase of the discharge, starting from a Maxwellian velocity distribution of the electron component. The model was experimentally tested by measurements of the small signal amplification as well as the ignition and burn voltage on a short duration spark preionized excimer laser. Calculations and experiments show that the magnitude of perturbations and the time constant of their development strongly depend on the laser gas composition. The results are especially important for the extension of the laser pulse which is the first step towards an improvement of the beam quality. ESA

(DE94-006613; UCRL-JC-114260; CONF-931018-83) Avail: CASI HC A02/MF A01

The MTX explored the plasma heating effects of 140 GHz microwaves from both gyrotrons and from the IMP FEL wiggler. The gyrotron was long pulse length (0.5 seconds maximum) and the FEL produced short pulse length, high peak power, single and burst modes of 140 GHz microwaves.

Full-power operations of the IMP FEL wiggler were commenced in April 1992 and continued into October 1992. The Experimental Test Accelerator 2 (ETA-2) provided a 50-nanosecond, 6-MeV, 2 to 3 k-Amp electron beam that was introduced colinear into the IMP FEL with a 140 GHz gyrotron master oscillator (MO). The FEL was able to amplify the MO signal from approximately 7 kW to peaks consistently in the range of 1 to 2 GW. This microwave pulse was transmitted into the MTX and allowed the exploration of the linear and nonlinear effects of short pulse, intense power in the MTX plasma. Single pulses were used to explore and gain operating experience in the parameter space of the IMP FEL, and finally evaluate transmission and absorption in the MTX. Single-pulse operations were repeatable. After the MTX was shut down burst-mode operations were successful at 2 kHz. This paper describes the IMP FEL, microwave transmission system to MTX, the diagnostics used for calorimetric measurements, and the operations of the entire microwave system. A discussion of correlated and uncorrelated errors that affect FEL performance is made. Linear and nonlinear absorption data of the microwaves in the MTX plasma is presented. DOE

The Atomic Vapor Laser Isotope Separation (AVLIS) program has been using laser absorption spectroscopy to monitor vapor densities for over 15 years. Laser absorption spectroscopy has proven itself to be an accurate and reliable method to monitor both density and composition. During this time the diagnostic has moved from a research tool toward a robust component of a process control system. The hardware used for this diagnostic is discussed elsewhere at this symposium. This paper describes how the laser absorption spectroscopy diagnostic is used as a component of a process control system as well as supplying detailed measurements on vapor densities, composition, flow velocity, internal and kinetic temperatures, and constituent distributions. Examples will be drawn from the uranium AVLIS program. In addition, potential applications such as composition control in the production of metal matrix composites or aircraft alloys will be discussed. DOE

New kinds of semiconductor microcavity lasers are being created by modern semiconductor technologies like molecular beam epitaxy and electron beam lithography. These new microcavities exploit 3-dimensional architectures possible with epitaxial layering and surface patterning. The physical properties of these microcavities are intimately related to the geometry imposed on the semiconductor materials. Among these microcavities are surface-emitting structures which have many useful properties for commercial purposes. This paper reviews the basic physics of these microstructured lasers. DOE

LARGE-AREA CONDITIONING OF OPTICS FOR HIGH-POWER LASER SYSTEMS
L. M. Sheehan, M. R. Kozlowski, F. Rainer, and M. C. Staggs 21 Dec. 1993 10 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-007028; UCRL-JC-114998; CONF-931054-8) Avail: CASI HC A02/MF A01

In order to reach the high fluence goals of the Beamlet laser at Lawrence Livermore National Laboratory (LLNL), the polarizers in the system must be laser conditioned to increase their damage thresholds. Research has shown that by using a six-step raster conditioning program, the damage thresholds of the HfO2/SiO2 multilayer polarizer coatings can be increased to meet the Beamlet 3-ns design goal of 8 J/cm(exp 2). Because of the large size of the polarizers (73 cm by 37 cm by 9 cm), a large-area conditioning facility was constructed capable of rastering a one-meter optic, weighing as much as 400 pounds, at any specified use angle. A large translational stage moves the optic in a raster pattern through a stationary, 10-Hz rep-rated, 1064-nm beam with 10-ns pulses. A scatter measurement diagnostic allows on-the-fly evaluation of laser induced damage and logs the coordinates of the damage. Laser energy is measured pulse-to-pulse in order to ensure stability during a scan. A small amount of minor coating damage does occur during the process, but the damage does not grow upon further irradiation. This damage causes only a small increase in total scatter compared to that due to the preexisting defects, and would not influence the system performance. DOE

STUDY OF THE DYNAMICS OF A NONLINEAR COUPLED-CAVITY LASER SYSTEM M.S. Thesis [ETUDE DE LA DYNAMIQUE D'UN SYSTEME LASER A CAVITE COUPLEE NON LINEAIRE]
Francois Martin Jul. 1993 100 p In FRENCH
(ISBN-0-315-86717-5; CTN-94-61225) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A study was conducted with the objective of demonstrating the possibility of generating ultrashort pulses by coupling a nonlinear Fabry-Perot interferometer with a continuous Nd-YAG laser. It is shown that the response of a nonlinear Fabry-Perot interferometer can become complex if the incident intensity is sufficiently high. In effect, it is possible to observe bistable or chaotic behavior, phenomena which are not yet treated in the literature on cavity lasers coupled to a nonlinear interferometer. An analysis is then presented of the dynamics of coupling between a cavity laser and interferometer. The analysis takes into account such concepts as the time for establishing a synchronized mode regime and the nonlinearity level to be exceeded for operating the laser system in the synchronized mode regime or the commutation regime. Different experimental configurations are studied, and a proposal is finally developed for a final configuration which should generate a continuous train of short pulses. CISTI

In many signal processing applications, the required information is usually found in the frequency contents of the signals to be analyzed. In most cases, Fourier transforms are used for the analysis, but this kind of transform is unable to provide temporal information. This problem can be overcome by using time-frequency transforms. A study is presented of a particular time-frequency transform called the wavelet transform, which is used as a basic tool in the design of a monitor for nondestructive testing. The instrument must be able to detect defects in materials and determine their positions. The algorithms used in the study are described, and three approaches are developed and implemented: vector processing, parallel processing, and special purpose very large scale integration architectures. Models were built and simulated, and it is shown that this work can be integrated in a high-level synthesis tool for special purpose signal processing architectures. Author (CISTI)

LASER APPLICATIONS IN WOOD PROCESSING
B. M. Broenstad, N. Auman, and K. Toennessen 27 Aug. 1993 11 p Presented at the Fourth NOLAMP Conference, Soenderborg, Norway, Aug. 1993 Prepared in cooperation with Selskapet for Industriell og Teknisk Forskning, Trondheim, Norway
(PB94-138567; ISBN-82-595-7449-7) Avail: Issuing Activity (National Technical Information Service (NTIS))

Lasers have been used for special woodprocessing purposes for more than twenty years. Besides dieboard manufacturing, which was one of the earliest applications, CO2 lasers are also used for different cutting, marking and engraving operations. High quality slots in varying depths are produced in wood and different plywood materials at high cutting speeds and with excellent accuracy. Decorative marking operations are performed by means of masking techniques, or by moving a defocused beam over the workpiece. Formerly collected and stored data is directly used for laser cutting of card-board and 3D map modeling. Examples of products are shown, processing data given and limitations discussed. NTIS

METHODS FOR SBS THRESHOLD REDUCTION Final Report
A. M. Scott (Defence Research Agency, Malvern, England.), W. T. Whitney, and M. T. Duignan 30 Jan. 1994 59 p
(AD-A276554; NRL/FR/5640-94-9704) Avail: CASI HC A04/MF A01

We have investigated methods for reducing the threshold for stimulated Brillouin scattering (SBS) using a frequency-narrowed Cr,Tm,Ho:YAG laser operating at 2.12 micrometers. The SBS medium was carbon disulfide. Single-focus SBS and threshold reduction by using two foci, a loop, and a ring have been demonstrated. Theories for the loop-SBS and the ring-SBS geometries have been developed and compared with experimental results. Backscatter power, energy, and conjugate fidelity data are presented. DTIC

MECHANISMS OF LASER INDUCED REACTIONS IN OPAQUE HETEROGENEOUS ENVIRONMENTS Final Report
F. Wilkinson Nov. 1993 209 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAJA45-90-C-0022)
(AD-A276642; R/D-6294-CH-01) Avail: CASI HC A10

The technique of laser flash photolysis has been applied to both heterogeneous and homogeneous samples in order to increase understanding of the mechanisms of laser induced reactions at surfaces. Nanosecond diffuse reflectance laser flash photolysis has been used to study triplet state absorption and fluorescence emission of monomers and dimers of acridine orange and other dyes which are shown to aggregate when adsorbed on microcrystalline cellulose and on other surfaces. The properties of excited states within dyed fabrics have been evaluated in several cases. The mechanism of the yellowing of thermomechanical paper pulp has also been investigated and transients studied on nanosecond timescales for the first time. Triplet-triplet energy transfer from benzophenone to oxazine dyes, from eosin to anthracene, and from anthracene to azomethine dyes has been studied on both cellulose and silica surfaces. This work demonstrates the occurrence of energy transfer by static and dynamic mechanisms depending on both the nature of the surface and the adsorbed species. The first picosecond studies exciting directly into the charge transfer absorption bands of aromatic hydrocarbon/oxygen complexes formed in the presence of high pressures of oxygen have been carried out to demonstrate the role of charge-transfer interactions in determining the singlet oxygen formation efficiencies during quenching of electronically excited states by molecular oxygen. Nanosecond laser excitation of a series of naphthalene and anthracene derivatives in the presence and absence of oxygen has clearly demonstrated for the first time the importance of charge transfer interactions in determining oxygen quenching constants and singlet oxygen formation efficiencies. IMPACT OF OBSERVED HYPERFINE SPLITTING ON X-RAY LASER GAIN
J. Nilsen, J. A. Koch, J. H. Scofield, B. J. MacGowan, J. C. Moreno, and L. B. DaSilva Nov. 1993 6 p Presented at the 9th American Physical Society (APS) Topical Conference on Atomic Processes in Plasmas, San Antonio, TX, 15 Nov. 1993
(Contract W-7405-eng-48)
(DE94-005822; UCRL-JC-114568; CONF-9311168-1) Avail: CASI HC A02/MF A01

Line broadening mechanisms play an important role in determining the gain of X-ray laser transitions. Typically Doppler broadening is the primary mechanism which determines the linewidth of these transitions. However, the authors present cases where the hyperfine effect is the dominant line broadening mechanism. Studying laser lines, which tend to have gain narrowed linewidths, enables one to observe these dramatic hyperfine effects which would be difficult to observe in opacity or Stark broadened lines. In this work the authors report the observation of hyperfine splitting on an X-ray laser transition and discuss how hyperfine splitting has a major impact on the laser gain. In the experiments they measure the lineshape of the 3p to 3s, J = 0 to 1 transition in neon-like niobium and zirconium and observe a 28 m-angstrom splitting between the two largest hyperfine components in the niobium(Z=41) line at 145.9 angstroms, in good agreement with theory. In zirconium(Z=40), no splitting is observed since the hyperfine effect is proportional to the nuclear moment, and zirconium has zero nuclear moment, as is typical for even-Z elements. The hyperfine effect is shown to effect transitions which have a 2p(sub 1/2) vacancy in the closed neon-like core much more than those with a 2p(sub 3/2) vacancy. A comparison of the neon-like niobium laser spectrum with that of zirconium shows a dramatic reduction in the relative intensity of the niobium laser lines with the 2p(sub 1/2) vacancy. The authors also report the unusual behavior noticed recently in low-Z neon-like X-ray lasers in which ions with odd Z lase poorly, if at all, relative to ions with even Z. The hyperfine effect is shown to have a substantial impact on the gain of the low-Z and helps explain their poor performance. DOE

HIGH CONVERSION EFFICIENCY PUMPED-CAVITY SECOND HARMONIC GENERATION OF A DIODE LASER
D. M. Keicher Jan. 1994 114 p
(Contract DE-AC04-94AL-85000)
(DE94-006805; SAND-93-0909) Avail: CASI HC A06/MF A02

To investigate the feasibility of producing a compact, efficient blue laser source, pumped-cavity second harmonic generation of diode lasers was explored. It is desirable to have such lasers to increase optical disk storage density, for color displays and for under-the-sea green-blue optical signal transmission. Based on assumed cavity losses, a cavity was designed and numerical analysis predicted an overall conversion efficiency to the second harmonic wavelength of 76% from a 75 mW diode laser. The diode laser used in these experiments had a single longitudinal and a single transverse mode output at 860 nm. The best conversion efficiency obtained (26%) was less than optimum due to the 2.5% single-pass linear losses associated with the cavity. However, calculations based on these higher losses are in good agreement with the experimentally determined values. In addition, a factor of 1.65 increase in the second harmonic output power is anticipated by reducing the input mirror reflectivity to better impedance-match the cavity. With this relatively low second harmonic conversion, the power to light conversion is 7.8%. DOE

FUSION APPLICATIONS OF HIGH POWER MILLIMETER WAVE SOURCES

R. L. Freeman and T. V. George Jan. 1994 2 p Presented at the International Conference on Millimeter and Submillimeter Waves, San Diego, CA, 10-14 Jan. 1994

(Contract DE-AC03-89ER-52153)

(DE94-007374; GA-A-21517; CONF-940132-1) Avail: CASI HC A01/MF A01

Heating by means of high power electron cyclotron (EC) waves in the mm wavelength range is considered to be one of the most attractive approaches for heating fusion plasmas to the temperatures required to achieve ignition. EC waves have also been used to drive plasma current by using directional launch and to stabilize MHD instabilities in tokamak plasmas through localized heating or current drive. Experiments are planned on both JET and TFTR to measure the alpha particle distribution by scattering EC waves. DOE

SOL-GEL COATINGS FOR HIGH POWER LASER OPTICS: PAST, PRESENT, AND FUTURE

I. M. Thomas 21 Dec. 1993 11 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993

(Contract W-7405-eng-48)

(DE94-007240; UCRL-JC-115120; CONF-931054-9) Avail: CASI HC A03/MF A01

An investigation into the preparation of sol-gel coatings for high power lasers was started at LLNL in 1983 and AR coatings were successfully developed for use in the Nova laser in 1984. Several other large lasers now use these coatings. Subsequent work on HR coatings resulted in AlOOH/SiO2 and later ZrO2 or HfO2/SiO2 systems of good optical performance. The use of organic polymer binders gave increased damage threshold and enhanced optical performance. We are in the process of scaling up HR fabrication for substrates approximately 38 cm square. Concurrently we are developing sol-gel random phase plates for laser beam smoothing. These have a patterned surface design of silica which induces phase shifts in the beam by variation in the optical path length. Plates of this type on 80 cm diameter substrates have been used successfully on the Nova. DOE

TI:SAPPHIRE BASED ULTRAFAST PUMP-PROBE LASER SOURCE IN THE VIOLET AND ULTRAVIOLET

G. Rodriguez, J. P. Roberts, and A. J. Taylor 1994 10 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994

(Contract W-7405-eng-36)

(DE94-007542; LA-UR-94-502; CONF-940142-26) Avail: CASI HC A02/MF A01

Frequency conversion of an ultrafast 810 nm Ti:sapphire laser has produced 15 mJ, 165-fs pulses at 405 nm with an energy conversion efficiency of 35%. Upon tripling the fundamental to 270 nm, an energy of 0.8 mJ is obtained. Unconverted to 405-nm light is used to generate an ultrafast supercontinuum in water that extends from 200 nm to 600 nm. The system operates at a 5 Hz repetition rate, and is useful for applications in deep ultraviolet pump-probe ultrafast spectroscopy. DOE

BACKSCATTER AND TRANSMISSION OF AEROSOL AT UV THROUGH MIDDLE IR WAVELENGTHS Interim Report No. 3, Mar. - Jun. 1993

7 Dec. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DAJA45-92-C-0024)

(AD-A277127; R/D-6798-EN-01) Avail: CASI HC A03

Simultaneous measurements of backscatter and transmission coefficients, sigma(sub b) and sigma(sub e), for obscuring and biological aerosols using a Nd:YAG pulsed laser system at 1064, 532, and 266 nm wavelengths are being investigated in the laboratory. The experimental arrangement has been satisfactorily tested at 1064 and 532 nm for well-characterized water drops yielding sigma(sub e) = 14.4 +/- 0.4 sigma(sub b) and sigma(sub e) = (53.1 +/- 3.2) sigma(sub b) respectively. A catalogue of pollen and spore species measured at Mace Head using a seven-day recording volumetric spore trap is presented. Pollen number concentration for individual pollen species is presented for April 1993 whilst total number concentration is presented for April and May 1993 at Mace Head for both pollen and spore species. PHOTOTHERMAL LASER DEFLECTION, AN INNOVATIVE TECHNIQUE TO MEASURE PARTICLES IN EXHAUSTS Final Report, Aug. 1989 - Feb. 1990

Cecil F. Hess Oct. 1993 48 p

(Contract F08635-89-C-0350)

(AD-A277151; AFESC/ESL-TR-90-16) Avail: CASI HC A03/MF A01

Photothermal Laser Deflection (PLD) is an analytical technique to measure in real-time the mass concentration of particles and gaseous exhaust pollutants in a variety of combustion devices (e.g., gas turbine engines and rockets). PLD uses a pump laser to locally heat the particle or gaseous species, thus changing the refractive index of the surrounding gas to form a thermal lens. A probe laser beam travelling through the thermal lens is temporarily deflected, and the amount of deflection is proportional to the species mass concentration. The experiments and analyses conducted during phase 1 demonstrated the feasibility of PLD in measuring the mass concentration of both soot particles and NO2 at a repetition rate of 25 HZ. PLD response was linear at soot concentrations from 0.3 to 10 mg/cubic meters at NO2 concentrations from approximately 6 to 208 ppm. Strategies to measure lower concentrations have been defined and include focusing the probe beam onto the face of the bi-cell detector. The large dynamic range, fast acquisition rate, and ability to measure particulate and gaseous pollutants makes PLD superior to other available methods. DTIC

GYROTRONS AND FREE ELECTRON LASERS FOR ATMOSPHERIC SENSING Interim Report

Wallace M. Manheimer 28 Feb. 1994 69 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A277281; NRL/MR/6707-94-7444) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The development of gyrotrons and free electron lasers over the past decade and a half have naturally led to investigations of additional applications for them. This work looks into applications in the area of atmospheric sensing. Specific gyrotron applications include cloud radars, sensors for atmospheric turbulence, and measurement schemes for upper atmosphere trace impurities. To be useful as atmospheric sensors, free electron lasers must be made much more compact. Several development strategies for accomplishing this are possible. It appears that there are numerous potential applications for both gyrotrons and free electron lasers as atmospheric sensors. DTIC

LASER FLASH PHOTOLYSIS, EPR AND RAMAN STUDIES OF LIQUIDS AT ELEVATED PRESSURES

E. M. Eyring 19 Nov. 1993 6 p

(Contract DE-FG03-93ER-14340)

(DE94-008351; DOE/ER-14340/1) Avail: CASI HC A02/MF A01

A laser flash photolysis kinetic study of a W(CO)(sub 5) intermediate reacting with several different substituted 2,2(prime)-bipyridine ligands at pressures up to 150 MPa in liquid toluene has confirmed the considerable influence of steric hindrance on the mechanism of a thermal ring closure reaction. A similar laser flash photolysis kinetic study has been carried out with Mo(CO)(sub 6) and several bidentate ligands resembling 2,2(prime)-bipyridine dissolved in supercritical carbon dioxide. A much larger negative activation volume is found in supercritical carbon dioxide than observed previously with this solute system dissolved in liquid toluene. Rate of replacement of one polydentate ligand by another stronger chelating agent in the first coordination sphere of aqueous gadolinium(III) ion was measured over a range of pressures and other variables using a stopped-flow spectrophotometer. Two consecutive first order reaction steps are observed that show acid-catalysis. DOE

CHEMISORBED-MOLECULE POTENTIAL-ENERGY SURFACES AND ELECTRONICALLY-STIMULATED PROCESSES
D. R. Jennison, E. B. Stechel, A. R. Burns, and S. Y. Li 1994 15 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-007932; SAND-94-0317C; CONF-940142-22) Avail: CASI HC A03/MF A01

Three topics illustrate some central physics of processes produced by UV-laser and low-energy electron stimulation. First, a multidimensional ground-state potential energy surface (PES) for NH3:Pd(111), computed using ab initio local-density functional theory, allows dramatically different dynamics depending on poorly-known excited-state forces. We use quantum-resolved experimental data to argue that stimulated desorption is dominated by a direct path off the surface, following placement of the wavepacket on a molecule-surface hard wall accessed by internal molecular motion. This illustrates the questionable relevance of one dimensional models for understanding molecule-surface dynamics. Second, we study the image-charge model of excited state forces experienced by ions produced, for example, by hot carrier attachment. Ab initio results show that this model totally fails at molecule-surface distances typical of chemisorption. Finally, we present a purely electronic adiabatic model of excited state PESs and use it to argue that, if significant covalent interactions occur between an adsorbate and a surface, hot carrier attachment does not simply produce singly-charged ions. Instead, attachment creates excitations of the molecule-surface bond occur and, in some cases, may result in multiply-charged ions. DOE

HIGH SPEED, STRAINED LAYER, MULTIQUANTUM WELL, GaInAsP AND GaAs LASERS AND HETEROSTRUCTURES Final Report
John Bowers, Larry Coldren, Gary Y. Robinson, and M. J. Hafich Dec. 1993 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-89-K-0042; ARPA Order 7144)
(AD-A277287; RL-TR-93-241) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report is divided into three sections, the first covering the work done in the area of high speed InGaAs/GaAs strained quantum well lasers, the second in the material growth and laser fabrication in the InGaAs/AlInGaAs system, and the third in the gas source molecular beam epitaxy (GSMBE) of In materials. This contract began at a time when quantum well laser bandwidths were severely limited for unknown reasons and the largest bandwidths were in bulk lasers. This has all changed now. Strained quantum well lasers were fabricated during the initial phase of this program resulting in anomalously large damping rates in quantum well lasers. Large damping rates result in small bandwidth because the lasers become critically damped at a low frequency. During the second portion of the contract, a theory describing the reasons for the resonance frequency, damping frequency, K factor, intensity noise, internal efficiency, injection efficiency, and wavelength chirping has been derived. Theoretical and experimental evidence in this program shows that carrier transport can lead to significant low frequency parasitic-like rolloff that reduces the modulation response by as much as a factor of six in quantum well lasers. A HISTORICAL PERSPECTIVE ON FIFTEEN YEARS OF LASER DAMAGE THRESHOLDS AT LLNL
F. Rainer, F. P. DeMarco, M. C. Staggs, M. R. Kozlowski, L. J. Atherton, and L. M. Sheehan 21 Dec. 1993 14 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-007930; UCRL-JC-114997; CONF-931054-10) Avail: CASI HC A03/MF A01

We have completed a fifteen year, referenced and documented compilation of more than 15,000 measurements of laser-induced damage thresholds (LIDT) conducted at the Lawrence Livermore National Laboratory (LLNL). These measurements cover the spectrum from 248 to 1064 nm with pulse durations ranging from less than 1 ns to 65 ns and at pulse-repetition frequencies (PRF) from single shots to 6.3 kHz. We emphasize the changes in LIDTs during the past two years since we last summarized our database. We relate these results to earlier data concentrating on improvements in processing methods, materials, and conditioning techniques. In particular, we highlight the current status of antireflective (AR) coatings, high reflectors (HR), polarizers, and frequency conversion crystals used primarily at 355 nm and 1064 nm. DOE

X RAY IMAGING AND X RAY SOURCE DEVELOPMENT AT LAWRENCE LIVERMORE NATIONAL LABORATORY
J. Trebes, R. Balhorn, and E. Anderson Dec. 1993 8 p Presented at the 4th International Conference on X Ray Microscopy, Chenogolovka, Russia, 20-24 Sep. 1993
(Contract W-7405-eng-48)
(DE94-007077; UCRL-JC-115163; CONF-9309290-2) Avail: CASI HC A02/MF A01

The Laser Program at Lawrence Livermore National Laboratory has a continuing effort to develop both x-ray sources and x-ray microscopy. This effort includes the ongoing development of: (1) a wide range of x-ray lasers at the Nova Laser Facility; (2) a zone plate lens--multilayer mirror based x-ray microscope; (3) three dimensional, high resolution x-ray microscopy; (4) short wavelength, normal incidence multilayer x-ray mirrors; (5) compact, high average power lasers for producing x-ray lasers and laser plasma x-ray sources. We have constructed and operated an x-ray laser based transmission x-ray microscope. The advantage offered by the x-ray laser source is the extreme high brightness allows high resolution images to be made on a timescale faster than that for x-ray damage effects to appear. The microscope, consists of the x-ray laser, a multilayer coated, near normal incidence spherical mirror used as a condenser, a silicon nitride specimen holder, an x-ray zone plate used as an objective lens, and a microchannel plate x-ray detector. The x-ray laser used is the Ni-like Ta x-ray laser operating with a wavelength of 4.48 nm, a pulselength of 200 spec, a divergence of 10 mrad, and an output energy of 10 microjoules. DOE

HIGH POWER SWITCH DESIGN FOR THE NOVA UPGRADE LASER (PROJECT HERCULES: HIGH ENERGY RESEARCH CONCERNING THE ULTIMATE LIFETIME OF EXPERIMENTAL SWITCHES) Final Report, 15 Aug. 1991 - 31 May 1993
Michael Giesselmann 1993 23 p Prepared for LANL, NM
(Contract W-7405-eng-48)
(DE94-007921; UCRL-CR-116290) Avail: CASI HC A03/MF A01

A test facility was constructed to test high power ignitrons using an electrolytic bank. The goal of this project, which was named Hercules (High Energy Research Concerning the Ultimate Lifetime of Experimental Switches), was to test the lifetime and switching characteristics of high power ignitrons for Lawrence Livermore's laser upgrade program. The main tubes of interest that have been tested were the NL-9000A from Richardson Electronics and the BK-1002 from English Electric Valve (EEV). Both tubes have stainless steel, cup style anodes. Both tubes were connected in series for the tests. Required test parameters were Ipeak = 300 kA and Qtransfer = 200 C. During the tests, the BK-1002 tube failed due to ignitor shorting. The average forward voltage drop across the EEV tube was almost twice than the drop across the NL-9000A. After the tube failure, the BK-1002 was replaced by a NL-1057 to continue testing of the NL-9000A. DOE

SUPERLUMINOUS LASER PULSE IN AN ACTIVE MEDIUM
D. L. Fisher and T. Tajima Dec. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG05-80ET-53088)
(DE94-007110; IFSR-635; DOE/ET-53088/635) Avail: CASI HC A03

Physical conditions are obtained to make the propagation velocity of a laser pulse and thus the phase velocity of the excited wake be at any desired value, including that equal to or greater than the speed of light. The provision of an active-plasma laser medium with an appropriately shaped pulse allows not only replenishment of laser energy loss to the wakefield but also acceleration of the group velocity of photons. A stationary solitary solution in the accelerated frame is obtained from the model equations and simulations thereof for the laser, plasma and atoms. This approach has applications in photonics and telecommunications as well as wakefield accelerators. DOE

HIGH-ENERGY CHEMICAL PROCESSES: LASER IRRADIATION OF AROMATIC HYDROCARBONS
A. D. Trifunac, A. D. Liu, and D. M. Loffredo 1994 6 p
(Contract W-31-109-eng-38)
(DE94-008107; ANL/CHM/PP-74944) Avail: CASI HC A02/MF A01

Recent studies of the high-energy photochemical degradation of polycyclic aromatic hydrocarbons (PAH's) in solution have furthered our fundamental understanding of the way in which radiation interacts with matter. A new comprehensive mechanism that unifies many of the seemingly contradictory observations in radiation and photochemistry has been proposed on the basis of evidence gathered using specialized techniques such as transient optical spectroscopy and transient dc conductivity. The PAH molecules were activated by two-photon ionization, and behavior of the transient ions were monitored as a function of photon energy. It was found that a greater percentage of ions retain sufficient energy to decompose when higher energy light was used. When these cations decompose they leave a trail of products that establish a 'high-energy' decomposition pathway that involves proton transfer from the ion, a mechanism hitherto not considered in photoionization processes. DOE

PUMP-PROBE METHOD FOR INVESTIGATING LASER ABLATION AND OPTICAL DAMAGE THRESHOLD MECHANISMS IN OPTICAL MATERIALS
L. L. Chase Sep. 1993 14 p Presented at the Nuclear Instruments and Methods in Physics Research on Radiation Effects in Insulators, Nagoya, Japan, Sep. 1993
(Contract W-7405-eng-48)
(DE94-008291; UCRL-JC-114770; CONF-9309259-5) Avail: CASI HC A03/MF A01

The method developed for investigating laser-surface interactions by measuring the ratio of ablation threshold fluence for a pair of picosecond or subpicosecond laser pulses to the single-pulse ablation threshold was applied to ZnS (wurtzite) and to the borosilicate glass BK-7. Each sample was exposed to 1000 pulse pairs of 580-nm dye laser radiation. For ZnS, linear absorption was found to be the cause of the cumulative optical damage mechanism; the linear absorption is probably caused by defects states (such as color centers) near the surface. The nonlinear behavior of BK-7 suggests that avalanche ionization could be the damage mechanism. Results for both materials show that intrinsic multiphoton absorption mechanisms may not be significant indicators of optical damage mechanisms even when they lead to very high free-carrier densities and energy absorption. DOE

SHORT-PULSE, HIGH-INTENSITY LASERS AT LOS ALAMOS
Antoinette J. Taylor, Jeffrey P. Roberts, George Rodriguez, Robert D. Fulton, George A. Kyrala, and Gottfried T. Schappert 1994 6 p Presented at the 11th International Workshop on Laser Interaction and Related Plasma Phenomena, Monterey, CA, 25-29 Oct. 1993
(Contract W-7405-eng-36)
(DE94-007545; LA-UR-94-528; CONF-931048-10) Avail: CASI HC A02/MF A01

Advances in ultrafast lasers and optical amplifiers have spurred the development of terawatt-class laser systems capable of delivering focal spot intensities approaching 10(exp 20) W/cm(exp 2). At these extremely high intensities, the optical field strength is more than twenty times larger than the Bohr electric field, permitting investigations of the optical properties of matter in a previously unexplored regime. The authors describe two laser systems for high intensity laser interaction experiments: the first is a terawatt system based on amplification of femtosecond pulses in XeCl which yields 250 mJ in 275 fs and routinely produces intensities on target in excess of 10(exp 18) W/cm(exp 2). The second system is based on chirped pulse amplification of 100-fs pulses in Ti:sapphire. DOE

A Cr:LiSAF laser has been successfully operated at time averaged powers up to 11 W and at pulse repetition rates to 12 Hz. During Q-switch operation, output energy as high as 450 mJ (32 ns FWHM) was obtained. Finally, line narrowed Q-switched pulses from the Cr:LiSAF laser were successfully used as a tunable light source for lidar to measure atmospheric water content. DOE

We discuss the use of a prepulse technique to achieve lasing in low-Z neon-like ions on the 3p yields 3s(J = 0 yields 1) transition. In neon-like titanium (Z=22), chromium (Z=24), iron (Z=26), nickel (Z=28), zinc (Z=30), and germanium (Z=32) this transition lases at 326, 285, 255, 231, 212 and 196 A, respectively. We present results using this technique on selenium (Z=34) and show how the J = 0 yields 1 transition at 182 A suddenly becomes a strong line. The observation that the low-Z ions with odd Z have not lased lead us to investigate the potential impact of hyperfine splitting on the laser gain. In our experiments we measure the lineshape of the 3p yields 3s(J = 0 yields 1) transition in neon-like niobium and zirconium and observe a 28 m(A) splitting between the two largest hyperfine components in the niobium (Z=41) line at 145.9 in good agreement with theory. In zirconium (Z=40), no splitting is observed since the hyperfine effect is proportional to the nuclear moment, and the principal isotopes of zirconium have zero nuclear moment, as is typical for even-Z elements. Finally, we discuss the use of low density foams for the laser target and present results which show lasing in zirconium aerogel with an initial density of 90 mg/cm(exp 3). DOE

Avail: CASI HC A02/MF A01

In recent work, a new class of magnetic multipoles based on planar configurations of permanent magnet (PM) materials was developed. These structures, in particular the quadrupole and sextupole, feature fully open horizontal apertures, and are comparable in effectiveness to conventional iron multipole structures. In this paper, results of recent measurements of planar PM quadrupoles and sextupoles are reported, and selected applications to FEL insertion device design are considered. DOE

A RELIABLE LOW-MAINTENANCE FLASHLAMP-PUMPED Ti:SAPPHIRE LASER OPERATING AT 120 PPS
K. H. Witte Mar. 1994 2 p Presented at the LASERS 1993 International Conference on Lasers and Applications, Lake Tahoe, NV, 6-10 Dec. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC03-76SF-00515)
(DE94-009030; SU-SLAC-PUB-6443; CONF-931237-9) Avail: CASI HC A01

Flashlamp-pumped Ti:sapphire lasers were reported to produce high-energy pulses with broad tunability. However, with the flashlamps operating at close to their explosion energy, and considering the thermal loading effects in the laser rod, these lasers were restricted to low repetition rates (typically around 10 PPS). Higher repetition rates at constant laser pulse energy reduce the flashlamp lifetime drastically. The author reports on a reliable flashlamp-pumped Ti:sapphire laser that was operating at 120 PPS for over 10(exp 9) shots with the only cavity or pump chamber maintenance being flashlamp changes less than every 2 x 10(exp 8) pulses--the lowest maintenance reported. A specular dual-lamp pump chamber was used to pump a 4 mm x 6 in., 0.1% doped Ti:sapphire rod. This resulted in a very low lasing threshold, which ensured a stable output at low pump levels. The criterion for pump power was to obtain a highly stable output at the edge of the selected tuning range, from 790 to 860 nm. The combination of flashlamp walls, flashlamp flow tubes, and rod solarization. DOE

A tunable solid state laser produces a laser emission at one or more wavelengths simultaneously. The tunable solid state laser includes a laser resonator defined by an output coupler reflective element, two fold mirrors, and one or more high reflectivity end elements to form a reflective path in a laser resonator cavity there between with a laser crystal disposed in the laser resonator cavity. A means for optically exciting the laser crystal is appropriately disposed for end pumping the laser crystal to produce a laser emission in a predetermined range of wavelengths. A wavelength dispersing element such as a prism is disposed in the laser resonator cavity between one of the fold mirrors and the high reflectivity end elements for tuning the laser emission at one or more of the desired wavelengths in the predetermined range of wavelengths, the dispersing element being transparent to the laser emission over the predetermined range of wavelengths. COMPARISON OF COHERENT TO INCOHERENT DETECTION AT 2.09 MICROMETERS USING A SOLID STATE LADAR SYSTEM Final Report, 27 Mar. 1991 - 21 Sep. 1993
Jay A. Overbeck Feb. 1994 128 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 0100)
(AD-A277159; WL-TR-94-1038) Avail: CASI HC A07

A 2.09 LADAR system has been built to compare coherent to incoherent detection. The 2.09 micron wavelength is of interest for its high atmospheric transmission and because it is eye safe. The 2.09 micron system presented within is capable of either a coherent or incoherent operational mode, is tunable in a small region around 2.09 microns, and is being used to look at the statistical nature of the LADAR return pulses for typical glint and speckle targets. In order to compare coherent to incoherent detection the probability of detection will be investigated as the primary performance criterion of interest. The probability of detection is dependent on both the probability of false alarm and the probability density function representing the signal current output from the detector. These probability distributions are different for each detection technique and for each type of target. Furthermore, the probability of detection and the probability of false alarm are both functions of the dominating noise source(s) in the system. A description of the theoretical expectations of this system along with the setup of the LADAR system and how it is being used to collect data for both coherent and incoherent detection will be presented. Results of Horizontal Propagation Experiment (HoPe) that was performed at the Phillips Laboratory Starfire Optical Range are presented. In this experiment, a laser beam was phase corrected using an adaptive optics system located at the transmitting site and focused toward a target located two miles away. Irradiance patterns of the corrected and uncorrected beam were recorded at the target site. Weather and atmospheric turbulence characteristics along the optical path were recorded at the same time. Strehl ratios calculated from the recorded images show that phase-only correction of a horizontally propagated laser beam can significantly improve the energy collected on-axis even under strongly scintillated conditions. Time-averaged Strehl ratios were improved by as much as a factor of five. Improvements in Strehl for varying turbulence conditions and the effect of hardware limitations on the results are discussed. VIBRATIONS OF A HEAVY TRUCK DIESEL ENGINE AND GEARBOX UNIT: EXAMINING STRUCTURE-BORNE SOUND TRANSMISSION WITH STATISTICAL ENERGY ANALYSIS M.S. Thesis
Bo Gaerdhagen and Bo-Goeran Emretsson Apr. 1993 96 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0283-8338)
(CTH-E-93-04; ETN-94-95952) Avail: Issuing Activity (European Space Agency (ESA))

Statistical Energy Analysis (SEA) is used for examining structure borne sound transmission in a heavy truck diesel engine and gearbox unit. SEA is considered to be applicable for frequencies above 1 kHz in the investigated case. The connection between the engine and the gearbox is not accurately described by the SEA model. This problem is circumvented by using two SEA models. The vibration transmission in the engine block is strongly influenced by in plane waves. The low modal count for the in plane waves reduces the prediction capability of the SEA model. Real noise sources in the engine and gearbox unit are complex. The examination was therefore limited to analysis using artificial excitation, simulating the sources. A rating of the relative strength of real noise sources in the engine and gearbox unit is presented. This rating is derived from measurements on a firing and externally driven engine. ESA

ROTORDYNAMIC EFFECTS DRIVEN BY FLUID FORCES FROM A GEOMETRICALLY IMPERFECT LABYRINTH M.S. Thesis
William C. Williston, Jr. Dec. 1993 43 p
(AD-A276424) Avail: CASI HC A03/MF A01

The forces on a rotor due to asymmetric pressure distributions resulting from a single gland non-circular labyrinth seal in a circular outer casing are analyzed for the purpose of understanding the possible causes of synchronous vibration due to seal intolerance. A lumped parameter model is developed for flow in the azimuthal direction inside the seal gland. The sealing knife imperfections causing the non-circularity may be due to manufacturing defects or in service ware. The resulting continuity and momentum equations are solved using a regular linear perturbation technique. Results from this model indicate under what conditions seal imperfections can generate forces of the same order of magnitude as rotor mass unbalance. DTIC

The development of a multiarm robotic system, where the practical implementation of the system involves motion coordination of two multijoint RTX robots with six degrees of freedom, hosted by a SPARC IPC workstation, is reported. A planning scheme is introduced to provide accurate and coordinated collision free motion. In addition, taking into account the need for high productivity in industrial environments, minimum time movements are imposed by increasing the manipulators' performance to a maximum, thus providing a high performance workcell. A real time case study is included to show the validity and efficiency of the system. ESA

CONTROL OF A FLEXIBLE SPACE ROBOT TRACKING A MOVING TARGET Ph.D. Thesis
Yi-Feng Chen 1993 109 p
Avail: Univ. Microfilms Order No. DA9323764

This dissertation is concerned with a space robot consisting of a rigid platform, two articulated flexible arms and a rigid end-effector. The task is to ferry some payload and to dock smoothly with an orbiting target whose motion is either known or not known a priori. The dynamical equations for planar motion of the space robot are derived by means of Lagrange's equations. They are then separated into two sets of equations suitable for rigid-body maneuver control design and vibration suppression control design. A perturbation method is used when the target motion is known a priori and direct partitioning is used when the target motion is not known. Both approaches are under the assumption that maneuver motions are much larger than elastic motions. As far as the rigid-body maneuver control is concerned, optimal trajectory planning is carried out off-line by means of the global optimization method under the assumption that the target motion is known a priori. In contrast, when the target motion is not known a priori, online feedback tracking control is carried out by means of an algorithm based on Liapunov-like methodology and using on-line measurements of the target motion. As far as the vibration suppression control is concerned, the use of the piezoelectric sensor/actuator pairs dispersed along the flexible arms is proposed. Collocated sensors/actuators for vibration control exhibit good performance. The actuators are designed to compensate for the disturbances caused by the rigid-body maneuver and to realize the LQR feedback control. Assuming that the number of actuators along each flexible arm is equal to the number of modes used to model the beam, the LQR control design is based on a linear time-varying system without persistent disturbances. Problems related to the digital implementation of the control algorithms are also discussed. Some undesirable effects, such as the bursting phenomenon and even system instability, can occur if the control algorithms are realized in discrete-time. To prevent these problems, the modified discrete-time control schemes are developed. Numerical examples are used to demonstrate the control algorithms. Dissert. Abstr.

SOLID-STATE RESISTANCE UPSET WELDING: A PROCESS WITH UNIQUE ADVANTAGES FOR ADVANCED MATERIALS
W. R. Kanne, Jr. 1993 18 p Presented at the 2nd Advanced Joining Technologies for New Materials, Cocoa Beach, FL, 2-4 Mar. 1994
(Contract DE-AC09-89SR-18035)
(DE94-005941; WSRC-MS-93-305; CONF-940367-1) Avail: CASI HC A03/MF A01

Solid-state resistance upset welding is suitable for joining many alloys that are difficult to weld using fusion processes. Since no melting takes place, the weld metal retains many of the characteristics of the base metal. Resulting welds have a hot worked structure, and thereby have higher strength than fusion welds in the same mate. Since the material being joined is not melted, compositional gradients are not introduced, second phase materials are minimally disrupted, and minor alloying elements do not affect weldability. Solid-state upset welding has been adapted for fabrication of structures considered very large compared to typical resistance welding applications. The process has been used for closure of capsules, small vessels, and large containers. Welding emphasis has been on 304L stainless steel, the material for current applications. Other materials have, however, received enough attention to have demonstrated capability for joining alloys that are not readily weldable using fusion welding methods. A variety of other stainless steels (including A-286), superalloys (including TD nickel), refractory metals (including tungsten), and aluminum alloys (including 2024) have been successfully upset welded. DOE

KINEMATIC SYNTHESIS AND ANALYSIS OF A NOVEL CLASS OF SIX-DOF PARALLEL MINIMANIPULATORS Ph.D. Thesis
Farhad Tahmasebi 1993 221 p
Avail: Univ. Microfilms Order No. DA9327504

A new class of six degree of freedom (six-DOF) parallel minimanipulators is introduced. The minimanipulators are designed to provide high resolution and high stiffness in fine-manipulation operations. Two-DOF planar mechanisms (e.g., five-bar linkages, pantographs) and inextensible limbs are used to improve positional resolution and stiffness of the minimanipulators. The two-DOF mechanisms serve as drivers for the minimanipulators. The minimanipulators require only three inextensible limbs and, unlike most of the six-limbed parallel manipulators, their direct kinematics can be reduced to solving a polynomial in a single variable. All of the minimanipulator actuators are base-mounted. As a result, higher payload capacity, smaller actuator sizes, and lower power dissipation can be obtained. Inverse kinematics of the minimanipulators has been reduced to solving three decoupled quadratic equations, each of which contains only one unknown. Kinematic inversion is used to reduce the direct kinematics of the minimanipulator to an eighth-degree polynomial in the square of a single variable. Hence, the maximum number of assembly configurations for the minimanipulator is sixteen. It is proved that the sixteen solutions are eight pairs of reflected configurations with respect to the plane passing through the lower ends of the three limbs. The Jacobian and stiffness matrices of two types of minimanipulators are derived. It is shown that, at a central configuration, the stiffness matrix of the first type minimanipulator (driven by bidirectional linear stepper motors) can be decoupled, if proper design parameters are chosen. It is also shown that the stiffness of the minimanipulators is higher than that of the Stewart platform. Guidelines for obtaining large stiffness values and for designing the drivers of the second type minimanipulator (simplified five-bar linkages) are established. An algorithm is developed to determine the workspace of the minimanipulators. Given any orientation for the output link, three dimensional representation of the workspace is obtained. Guidelines for avoiding discontinuities inside of the workspace are established. Necessary and sufficient conditions for both inverse and direct kinematics singularities of the minimanipulators are obtained. Guidelines for avoiding direct kinematics singularities, which occur within the minimanipulator workspace, are established. Dissert. Abstr.

REMOTE ROBOT MANIPULATOR COUPLED WITH REMOTE-CONTROLLED GUIDE VEHICLE FOR SOIL SAMPLING IN HAZARDOUS WASTE SITES Ph.D. Thesis
Kiho Kim 1993 127 p
Avail: Univ. Microfilms Order No. DA9321180

The important initial step for remediation of hazardous waste is contaminant analysis since the cleanup operation can not begin until the contaminants in hazardous waste sites have been clearly identified. Ames Laboratory, one of the U.S. Department of Energy sites, has developed a robotic sampling system for automation of real-time contaminant analysis in situ which will provide the advantage of lowering the cost per sample, eliminating personnel exposure to hazardous environments, and allowing quicker results. Successful accomplishment of real-time contaminant analysis will require a remote manipulator to perform the sampling tasks in remote and unstructured surroundings, and a remote-controlled guide vehicle to move a remote manipulator into the desired sampling location. This thesis focuses on the design and construction of a remote-controlled guide vehicle to move the robotic sampling system into the contaminated field to obtain soil samples at the desired locations, the development of an integrated dynamic model of a remote manipulator, the identification of dynamic parameters in the integrated dynamic model, and the design of a mobile robotic sampling system. A four-wheeled vehicle prototype has been constructed and its performance tested manually in the field to verify the design requirements. To remotely control the vehicle, mechanical requirements to activate the brake, throttle, transmission, and steering linkages were determined based on experimental results. A teleoperated control utilizing hundred feet long umbilical cords was first employed to remotely control the vehicle. Next, the vehicle was modified to remotely operate in the field by radio control without the aid of long umbilical cords, satisfying all the design specifications. To reduce modeling error in the robotic system, the integrated dynamic system comprised of a remote manipulator (located on a trailer pulled by the remote-controlled guide vehicle) and its drive system has been modeled. The friction model as a function of velocity is included. The dynamic parameters such as velocity-dependent friction and gravity torque in the integrated dynamic model have been determined based on experimental results. Finally, a robotic arm, a sampling tool, and a soil recovery fixture for a mobile robotic sampling system to be mounted on the remote-controlled guide vehicle have been designed and analyzed. The integrated dynamic model for the robotic arm (mounted on the remote-controlled guide vehicle) and its drive system has also been developed. Dissert. Abstr.

Nd-YAG LASER WELDING OF THE FIBER OPTIC CONNECTOR TO THE HEADER SHELL ON THE 2SL ACTUATOR
J. T. Adams and J. J. Kwiatkowski 14 Jan. 1994 12 p
(Contract DE-AC04-88DP-43495)
(DE94-006104; MLM-3790) Avail: CASI HC A03/MF A01

An investigation was completed to determine the feasibility of laser welding a fiber optic connector at a right angle to the header shell of the 2SL actuator. The work was completed at the request of Los Alamos National Laboratory (LANL). These studies showed a minimal temperature rise at the fiber-to-connector shell seal area and essentially no loss in light transmission after welding. Both metallographic sections and tensile pull-test failure values were obtained. This study proves feasibility and with minimal change in parameters the penetration can be easily increased, which will yield higher tensile pull-test failure values. DOE

SOOT AND LIQUID-PHASE FUEL DISTRIBUTIONS IN A NEWLY DESIGNED OPTICALLY ACCESSIBLE DI DIESEL ENGINE
J. E. Dec and C. Espey Oct. 1993 18 p Presented at the 1993 Diesel Emission Reduction Workshop, La Jolla, CA, Jul. 1993
(Contract DE-AC04-76DR-00789)
(DE94-005648; SAND-93-8690C; CONF-9307164-1) Avail: CASI HC A03/MF A01

Two-dimensional (2-D) laser-sheet imaging has been used to examine the soot and liquid-phase fuel distributions in a newly designed, optically accessible, direct-injection diesel engine of the heavy-duty size class. The design of this engine preserves the intake port geometry and basic dimensions of a Cummins N-series production engine. It also includes several unique features to provide considerable optical access. Liquid-phase fuel and soot distribution studies were conducted at a medium speed (1,200 rpm) using a Cummins closed-nozzle fuel injector. The scattering was used to obtain planar images of the liquid-phase fuel distribution. These images show that the leading edge of the liquid-phase portion of the fuel jet reaches a maximum length of 24 mm, which is about half the

combustion bowl radius for this engine. Beyond this point virtually all the fuel has vaporized. Soot distribution measurements were made at a high load condition using three imaging diagnostics: natural flame luminosity, 2-D laser-induced incandescence, and 2-D elastic scattering. This investigation showed that the soot distribution in the combusting fuel jet develops through three stages. First, just after the onset of luminous combustion, soot particles are small and nearly uniformly distributed throughout the luminous region of the fuel jet. Second, after about 2 crank angle degrees a pattern develops of a higher soot concentration of larger sized particles in the head vortex region of the jet and a lower soot concentration of smaller sized particles upstream toward the injector. Third, after fuel injection ends, both the soot concentration and soot particle size increase rapidly in the upstream portion of the fuel jet. DOE

AN EXPERIMENTAL AND ANALYTICAL INVESTIGATION OF A THREADED FASTENER [TUKIRUUVIN VAESYMISTARKASTELU]
Sisko Sipilae Nov. 1993 54 p In FINNISH Sponsored by Technology Development Center, and Technical Research Centre of Finland
(ISSN 1235-0613)
(VTT-JULK-786; ISBN-9-51-384134-0; ETN-94-96036) Copyright Avail: CASI HC A04/MF A01

The fatigue strength of a connecting rod consisting of a threaded bar and an integral lug end was analyzed both experimentally and analytically. Different geometries and manufacturing methods were considered. These included cut and rolled threads, lugs which were welded to the threaded bar or machined with the threads from a single piece of material, and rods both with and without a reduced section between the threads and lug end. Fatigue tensile tests showed the reduced section between lug and threads and sometimes the lug itself to be the weakest point of the component. The rods with a welded lug and a reduced section between threads and lug were found to have the highest fatigue strengths. Rolled threads showed higher fatigue strength than did cut threads at the endurance limit. All analytically determined fatigue limits were conservative compared to test results. ESA

JOINING OF ALUMINA BY VACUUM BRAZING [ALUMIINIOKSIDIN LIITTAEMINEN TYHJOEJUOTTAMALLA]
Liisa Heikinheimo, Mika Siren, and Pentti Kauppinen Aug. 1993 53 p In FINNISH Sponsored by Technology Development Center, and Technical Research Centre of Finland
(ISSN 1235-0605)
(VTT-TIED-1495; ISBN-9-51-384429-3; ETN-94-96039) Copyright Avail: CASI HC A04/MF A01

The active brazing method for diffusion bonding of ceramics to metals is addressed. This method is very flexible compared to the traditional Mo-manganese coating with subsequent brazing that includes four process steps: in active brazing the process is done in one step. The joint properties are favorable, the residual stress build up is limited if the braze is correctly selected and the thermal cycle is controlled, and the resulting strength and leak tightness are good. In experimental work the joinability of alumina to titanium and Ni superalloys was studied by wetting experiments, nondestructive test and shear strength measurements. The spreading of the braze is affected not only by the surface conditions of mating materials but also by the type of the brazing alloy. The Ag-Cu base alloys give better wetting, strength and leak tightness properties than the Ag base alloys. A shear test method was developed for the mechanical testing of metal-ceramic joints. However, the sample geometry affects the measured values, namely a smaller specimen size provides better results. The correlation between the C-SAM results, which describe the ratio between the true bonded area and unbonded area, and measured shear strength values is presented. The dependence between the measured strength and the area of the joint defects becomes obvious and should be studied in more detail. ESA

(ISBN-0-315-86323-4; CTN-94-61190) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Motion and force control methods are developed for coordinated robots assumed to grasp an object rigidly. The control problem is defined in a system theoretical framework where desired trajectories of motion and force are tracked asymptotically. Both joint redundant and nonredundant robots are considered. Four motion and force control problems are defined and solved. Motion and force control of coordinated robots in the presence of model uncertainty is developed based on an adaptive scheme used to estimate the unknown constant parameters of the robots, the object, and the environment. The problem of control of redundant robots in the presence of obstacles in the environment is addressed by defining the extended task space. The problem of optimal control of redundant robots focuses on minimizing torque loading at the joints; locally and globally optimal control laws are developed. Motion and force control of robots in the presence of joint flexibility is accomplished by developing a unified controller to regulate the motion, the contact and internal forces, and the joint elastic force, and to distribute the load between the robots. An experimental setup using two commercial robots has confirmed the results of the theoretical analysis. Author (CISTI)

A CONTRIBUTION TO THE REPRESENTATION AND IDENTIFICATION OF SEMI-FLEXIBLE ROBOTS M.S. Thesis [CONTRIBUTION A LA REPRESENTATION ET A L'IDENTIFICATION DES ROBOTS SEMI-SOUPLES]
Louise Cleroux Aug. 1992 105 p In FRENCH
(ISBN-0-315-86450-8; CTN-94-61197) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A representation model for a semi-flexible robot is developed from a combination of the usual Denavit Hartenberg (1955) model, a beam model for every link, and a spring model for every joint. Based on Castigliano's theorem, all the beam deflection modes are considered possible in addition to the springs. The model is able to represent three dimensional errors. Simulations of the model provide interesting results. Effects of arm postures and load categories on the flexible structure are easily visualized from the deformation surfaces obtained. Identification of nongeometric parameters is partially demonstrated using the minimization algorithms of Nelder-Mead (1964) and Powell (1964). The forces used in calculating the strain imposed are the ones felt at the robot base. With these, the three nongeometric parameters of a one degree of freedom planar robot are identified with two sets of data. The six nongeometric parameters of a two degrees of freedom planar robot have been identified with 97 percent success using only six sets of data. A subprogram was developed to calculate the forces at the robot base, based on the flexible structure and the tool tip forces. The nongeometric parameters for a one degree of freedom planar robot were then identified. Author (CISTI)

ROBOT GRASPING: STABILITY AND OPTIMIZATION ISSUES Ph.D. Thesis
K. Venugopal Varma 1993 134 p
Avail: Univ. Microfilms Order No. DA9327512

In many robotic applications, robot end effectors are used to grasp and manipulate objects. To obtain stable grasps, force and moment balances must be satisfied. Geometric constraints that guarantee force and moment balances are presented. The constraints are used for determining whether a set of finger/object contact points result in a stable grasp. It is recognized that appropriate contact points and sufficient finger forces are required for generating a stable grasp. A stable grasp can be viewed as a static equilibrium state of the object that is maintained when the end effector replaces the object's support. Once an object is grasped, one has to assess the grasping quality. Grasping quality is defined as the capacity of the grasp to resist external forces and moments (disturbances). Grasping quality can be formulated as a mathematical optimization problem in which the finger forces that minimize an objective function and balance the external disturbances are sought. The value of the objective function and the finger forces represent the quality of the grasp for given external disturbances. Three grasping quality (objective) functions are examined and their values together with the resulting finger forces are evaluated. A precision

grasp of a pencil with four finger contacts as used in handwriting is analyzed. A model of the grasp is developed and finger contacts are determined. The optimal finger contacts are evaluated for two different objective functions. This problem formulation results in finger contacts that closely resemble the contacts employed by human beings. The pencil grasping model was used to predict the normal pressure on the writing surface for different stroke directions. These pressure variations are compared with human handwriting samples that correlated well with the model results. The constraints that result in a stable grasp and the grasping quality measure provide the necessary information for assessing the success rate of mechanical grippers in performing complex tasks. Dissert. Abstr.

Planning, implementation, and validation of applications of robotized grasping are done most of the time on the basis of experiments or by trial and error on the manipulator itself. To avoid the resulting losses in time and money, it would be desirable to be able to develop a more rigorous approach for treating and validating cases of grasping by employing a computer simulation of the pressure and shear force distributions resulting from static and dynamic loadings in the grasper/object contact zones. A simplified model of distribution of pressure and shear stress in the contact zones has been developed based on the method of Winkler (elastic contact) and as a function of contact geometry. The validity of the grasping was defined taking account of the gravitational and dynamic force fields as well as the grasping force transmitted to the points of contact. Experiments on the GMF-S300 robot allowed testing of certain aspects of the proposed approach at different stages of the project. CISTI

HIGH TEMPERATURE NASP ENGINE SEAL DEVELOPMENT (Videotape)
1992 Videotape: 6 min. 25 sec. playing time, in color, with sound
(NASA-TM-109750; NONP-VT-94-9950) Avail: CASI VHS A01/BETA A22

This video details research being conducted at the Lewis Research Center on high temperature engine seal design for the National Aerospace Plane. To maximize the speed, the jets on the NASP extract oxygen from the air rather than carry large liquid fuel tanks; this creates temperatures within the jet of over 5000 F. To prevent these potentially explosive gases from escaping, researchers are developing new technologies for use in the engine seals. Two examples explained are the ceramic wafer seal and the braided ceramic rope seal. Computer simulations and laboratory footage are used to illustrate the workings of these seals. Benefits for other aerospace and industrial applications, as well as for the space shuttle, are explored. CASI

The issue of model identification of an advanced modular and reconfigurable robot system, the IRIS Facility, is addressed. Theoretical insights into the methodology of parameter estimation are developed and the theory is applied experimentally to the IRIS Facility. In the theoretical study, the classical least squares (LS) algorithm is presented. It is found that LS estimates contain bias when measurement noise is present. To compensate the bias in LS estimates, two modified LS algorithms are proposed: the bias compensating LS algorithm and the instrumental variables method. The applicability of these two algorithms to robot parameter estimation is discussed and evaluated by simulation examples. Using the proposed algorithms, the dynamic parameters of the IRIS Facility are determined experimentally. The results confirm the theoretical analysis that the modified LS estimates are more accurate than the original LS estimates. The experimental work also provides a set of reliable parameters for the facility users and control system designers. Recommendations are given for improving the estimation process and related issues. Author (CISTI)

AUTOMATIC ANALYSIS OF FORCE DISTRIBUTION IN MULTI-FINGERED ARTICULATED HANDS M.S. Thesis
Mahyar Amani 1993 154 p
(ISBN-0-315-87205-5; CTN-94-61253) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A kinematic and force analysis of multifingered, multijointed dexterous hands is presented. The analysis involves calculation of the basis for null space of the grasp matrix. An algorithm is developed to perform all necessary analyses of dexterous hands. All equality and inequality constraints are automatically formulated in a constraint matrix. These include unisense constraints, frictional constraints, and joint torque limits. The reduction of the constraint matrix into a compact form is also presented. The algorithm is written in Fortran and is user-friendly and capable of handling all practical grasping problems. Different types of contact may be examined, including soft finger contact and point contact with and without friction. The software can easily determine the feasibility of a grasp for a given set of contact forces/torques, and may potentially be combined with either routines to compute the optimum value of contact wrench intensities and joint torque values. CONTROL OF A FLEXIBLE-LINK ROBOTIC ARM MANIPULATING AN UNKNOWN DYNAMIC PAYLOAD Ph.D. Thesis
Lawrence John Alder 1993 180 p
Avail: Univ. Microfilms Order No. DA9317744

When light-weight space-based robots, such as the space shuttle's RMS (remote manipulator system), manipulate massive payloads such as satellites, significant structural bending is induced in the links of the robot. In addition, space-based robots will often manipulate payloads that are not rigid bodies: for example, satellites may contain fuel or have flexible appendages. This dissertation contributes new basic technology that will enable flexible-link manipulators to perform precise end-point control of payloads while simultaneously controlling the unknown internal dynamics of the payload. The approach taken here combines high-performance control with an innovative identification algorithm. In addition, to facilitate the development of controllers, a numerically efficient procedure to merge payload and arm dynamic models is presented. First, controllers incorporating end-point feedback with a known payload are made robust to high-frequency modelling errors, sensor noise, and sensor bias using frequency-weighted linear quadratic Gaussian design methods. Using end-point position measurements as the primary sensor, the robot is then capable of actively damping the internal payload dynamics an order of magnitude faster than the natural damping rate--if it knows the payload parameter. However, with this type of controller small parameter variations in the payload can lead to poor performance or instability. This research has therefore also developed an identification algorithm that updates the end-point controller parameters; this enables the system to achieve high performance when the payload dynamics are not known a priori. By using a nominal control law, the identification problem can be reduced to detecting and identifying eigenvalues of a closed system. To identify these eigenvalues, a generic algorithm capable of determining the eigenvalues of a system in real time has been developed: even the order of the system need not be known in advance. With this approach, moreover, the identification algorithm does not require that the system inject broad-band excitation in order to work accurately. An experimental robotic system was designed and built to test these emerging control strategies. All of the control strategies have been verified on the experimental robot. Experimental results demonstrate, for the first time, precision end-point control of a very flexible singlelink robot arm with unknown dynamic payloads. Dissert. Abstr.

PARALLEL METHODS FOR SYNTHESIZING WHOLE-HAND GRASPS FROM GENERALIZED PROTOTYPES

Nancy S. Pollard Jan. 1994 283 p

(Contracts N00014-91-J-4038; N00014-92-J-1814)

(AD-A276798; AI-TR-1464) Avail: CASI HC A13/MF A03

This report addresses the problem of acquiring objects using articulated robotic hands. Standard grasps are used to make the problem tractable, and a technique is developed for generalizing these standard grasps to increase their flexibility to variations in the problem geometry. A generalized grasp description is applied to a new problem situation using a parallel search through hand configuration space, and the result of this operation is a global overview of the space of good solutions. The techniques presented in this report have been implemented, and the results are verified using the Salisbury three-finger robotic hand. DTIC

PINCHED PROPAGATION OF HIGH-POWER, PULSED ELECTRON BEAMS FOR WELDING AND MATERIALS PROCESSING APPLICATIONS Interim Report

Richard F. Fernsler, Richard F. Hubbard, and Martin Lampe 3 Jan. 1994 59 p

(ARPA Order 7781)

(AD-A276925; NRL/MR/6790-93-7403) Avail: CASI HC A04/MF A01

Electron beams are used commercially as intense heating sources for welding and related materials processing applications. The beams used for welding operate continuously with energy up to 200 keV and current approximately 1 A. Because these beams are severely degraded by propagation in air over any substantial range, most present-day electron-beam welders require vacuum pumping and precision focusing, which has severely restricted utilization of the technology. Over the past few decades, a different class of electron-beam generators has been developed that produces pulsed beams with energies of several MeV, currents of 1 kA or more, radii as small as 1 mm, pulse lengths of tens of ns, and pulse repetition rates up to several kHz. We show here that beams of this type can propagate in ambient air, in a tightly pinched mode and with acceptable stability, over distances of a few tens of cm. We determine the constraints on the choice of beam parameters, due mainly to the effects of gas scattering and the resistive instability. We show that stability can be enhanced, and the acceptable parameter range extended considerably, by using a narrow conducting pipe filled with air or another gas to guide the beam to the workpiece. CORRELATION OF FLUX COMPOSITION AND INCLUSION CHARACTERISTICS WITH SUBMERGED ARC WELD METAL PROPERTIES IN HY-100 STEEL M.S. Thesis

Kent W. Kettell Sep. 1993 107 p

(AD-A277040) Avail: CASI HC A06/MF A02

Submerged arc weldments of HY-100 steel prepared under standard conditions with five commercially available fluxes were analyzed to discern a basis for the variation in mechanical properties associated with different flux use. The variations in flux chemistry resulted in alloyed weldments with diverse weld metal mechanical properties as evident by Charpy impact, tensile, dynamic tear, and microhardness tests. The microstructures and macrostructures were examined using optical and electron microscopy in order to determine the basis for the variations in strength and toughness. Scanning electron microscope and energy dispersive x-ray experiments were performed to determine the size, type, distribution and volume fraction of the non-metallic inclusions in the weld metal. Inclusion characterization revealed that the role of the flux in alloying had a more significant effect on the strength and toughness than did the presence of specific inclusions. DTIC

DEVELOPMENT OF LIGHTWEIGHT RADIATORS FOR LUNAR BASED POWER SYSTEMS

Albert J. Juhasz and Harvey S. Bloomfield May 1994 12 p Proposed for presentation at the 5th European Symposium on Space and Environmental Control Systems and the 24th International Conference on Environmental Systems, Friedrichshafen, Germany, 20-23 Jun. 1994; sponsored by ESA, SAE, ASME, AIChE, and AIAA

(RTOP 233-02-0B)

(NASA-TM-106604; E-8880; NAS 1.15:106604) Avail: CASI HC A03/MF A01

This report discusses application of a new lightweight carbon-carbon (C-C) space radiator technology developed under the NASA Civil-Space Technology Initiative (CSTI) High Capacity Power Program to a 20 kWe lunar based power system. This system comprises a nuclear (SP-100 derivative) heat source, a Closed Brayton Cycle (CBC) power conversion unit with heat rejection by means of a plane radiator. The new radiator concept is based on a C-C composite heat pipe with integrally woven fins and a thin walled metallic liner for containment of the working fluid. Using measured areal specific mass values (1.5 kg/m2) for flat plate radiators, comparative CBC power system mass and performance calculations show significant advantages if conventional heat pipes for space radiators are replaced by the new C-C heat pipe technology. NEW MICRO- AND MACROSCOPIC MODELS OF CONTACT AND FRICTION Final Technical Report, 1 Nov. 1990 - 31 Oct. 1993

W. W. Tworzydlo, W. Cecot, J. T. Oden, and C. H. Yew 29 Nov. 1993 185 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-91-C-0011)

(AD-A277240; TR-93-10; AFOSR-94-0045TR) Avail: CASI HC A09

This is the final report for the three year research project dedicated to the development of new asperity-based models of frictional interfaces. The main concept is to combine statistical homogenization methods with a realistic nonlinear finite element analysis of surface micro-asperities, and thus produce new asperity-based models of contact and friction. Research in the project started with the development of a complete theory and software for the statistical homogenization of random surface parameters. The next stage focused on the development of a finite element code for modeling surface asperities. This code is based on a proprietary h/p adaptive finite element kernel, which has been customized for the analysis of elastic and elasto-viscoplastic asperities with contact, molecular-range adhesion, and sliding resistance. To verify the new asperity-based interface models, special experiments were designed and performed for custom-shaped asperities and for rough engineering surfaces. The results of these experiments compare favorably with asperity-based theoretical and numerical predictions, and thus confirm the feasibility and practical value of the new models developed in this project. These models will be applicable in the analysis and control of a broad range of contact and friction phenomena, such as friction-induced squeaks and noises, tribology of bearings, electrical and thermal connectors, the mechanism of wear, and many others. AN EXPERIMENTAL TESTBED FOR A FREE-FLOATING MANIPULATOR M.S. Thesis

Douglas L. Maddox Dec. 1993 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A277350) Avail: CASI HC A03

The attitude control of a multibody system in a gravity free environment has been an ongoing field of study for decades. Although most methods involve the use of thrusters, some algorithms exist that utilize internal motion of the system for reorientation. These algorithms reduce the expenditure of the limited amount of onboard fuel so as to extend the useful life span of the system. An experimental facility for testing existing algorithms and algorithms to be developed in the future for motion planning of multibody space systems are developed as part of this research. The multibody system developed is comprised of a two link space vehicle/manipulator system. The system is mounted on air bearings and floats freely on a flat glass table. The robotic system is controlled in real time using a VME based controller with support from a SPARC station. DTIC

DESIGN OF A TWO DIMENSIONAL PLANER PRESSURIZED AIR LABYRINTH SEAL TEST RIG M.S. Thesis

Joseph S. Konicki Dec. 1993 86 p Limited Reproducibility: More than

20% of this document may be affected by microfiche quality
(AD-A277232) Avail: CASI HC A05

A two-dimensional planer labyrinth seal test rig was designed to operate with air supplied at 45 psig and temperatures up to 150 F. The rig operates with a manually specified test section pressure up to 30 psig yielding Mach numbers to 0.9 and gap Reynolds numbers to 100,000. The air flow rate through the seal will be controlled by setting inlet pressure and adjusting an outlet control valve. The test section measurements are 18 inches wide by 1.5 inches depth by 6 inches in length and provides for 10:1 large scale geometry seals to be used to facilitate measurements. Design maximum seal gap size is 0.15 inches. The test section has a glass viewing port to allow flow field measurement by non-intrusive means such as Laser Doppler Velocimeter (LDV) with seals containing up to 5 sealing knives. Measurements of pressure, temperature and flow fields can also be simultaneously measured by probes inserted in the seal itself, or mounted on the removable/replaceable top plate. Inlet flow is conditioned through the use of a dump diffuser incorporating screens, honeycombs, expansion and contraction portions. The inlet flow to the test section can be modified from uniform to various non-uniform conditions by employing profile generators such as screens and winglets. A detailed mechanical design has been conducted including stress analysis and seal flow rate predictions. DTIC

DEVELOPMENT OF AN AUTOMATED WIRE DELIVERY SYSTEM FOR ROBOTIC WELDING APPLICATIONS Final Report, 18 Apr. 1990 - 18 Jul. 1992
Timothy B. Morris 9 Jul. 1992 37 p
(Contract NAS8-38477; SBIR-05.05-2200)
(NASA-CR-194216; NAS 1.26:194216; NRC-TR-92-143) Avail: CASI HC A03/MF A01

Our Phase 1 study showed new techniques and procedures are required for maintaining the delivery of filler wire into the weld pool for robotic VPPA (variable polarity plasma arc) and GTA (gas tungsten arc) welding applications. Toward this end, the development and implementation of an autonomous wire delivery system appears very feasible utilizing existing proven technologies. In our Phase 1 research effort, we investigated the requirements necessary of a wire delivery system to assure a quality weldment. We also evaluated various sensing technologies for their ability to provide information related to delivery of the wire into the weld pool. Finally, we described the types of software necessary for the automatic wire delivery system. Several approaches for automating the wire delivery system have been suggested, and we recommend the building of a prototype system in our Phase 2 effort as a logical step in the application of this technology to robotic GTA and VPPA welding. Such a prototype would contain the necessary hardware components, sensors and control software for evaluating the performance of the system as applied to the berthing port, main engine and external fuel tank. This tool would be used to demonstrate the worth and plausibility of automating the wire delivery system for each of these applications. Author

A NEW SOLUTION METHOD FOR THE INVERSE KINEMATIC JOINT VELOCITY CALCULATIONS OF REDUNDANT MANIPULATORS
F. G. Pin, P. F. R. Belmans, J. C. Culioli, D. D. Carlson, and F. A. Tulloch 1994 8 p Presented at the Institute of Electrical and Electronics Engineers (IEEE) International Conference on Robotics, San Diego, CA, 8-13 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE94-004427; CONF-940550-10) Avail: CASI HC A02

A new analytical method to resolve underspecified systems of algebraic equations is presented. The method is referred to as the Full Space Parameterization (FSP) method and utilizes easily-calculated projected solution vectors to generate the entire space of solutions of the underspecified system. Analytic parameterizations for both the space of solutions and the null space of the system reduce the determination of a task-requirement-based single solution to a m - n dimensional problem, where m - n is the degree of underspecification, or degree of redundancy, of the system. An analytical solution is presented to directly calculate the least-norm solution from the parameterized space and the results are compared to solutions of the standard pseudo-inverse algorithm which embodies the (least-norm) Moore-Penrose generalized inverse. Application of the new solution method to a variety of systems and task requirements are discussed and sample results using four-link planar manipulators with one or two degrees of redundancy and a seven degree-of-freedom manipulator with one or four degrees of redundancy are presented to illustrate the efficiency of the new FSP method and algorithm. FLEXIBLE DRIVE SHAFT COUPLING Patent Application
Stanley Olson, inventor (to Navy) 12 Jul. 1993 21 p
(AD-D016096; US-Patent-Appl-SN-089915) Avail: CASI HC A03/MF A01

A flexible drive shaft coupling with two stage torsional flexibility is introduced. The flexible drive shaft coupling allows axial, radial, and bending misalignment of the input and output shafts while vibrationally isolating the shafts from one another. At low torque, power is transmitted from the input shaft through an elastomeric ring to the output shaft. At higher torque the elastomeric ring is deformed to allow contact between a less resilient snubber assembly and a drive plate mechanically connected to the output shaft. Power is transmitted through less resilient snubber assemblies which provide for greater power transmission. The axis of the coupling can be provided with a flexible spool assembly to allow transmission of exhaust mass from the input shaft to the output shaft. DTIC

CONTROL STRATEGIES FOR SYSTEMS WITH LIMITED ACTUATORS Final Report
Vincent R. Marcopoli and Stephen M. Phillips Apr. 1994 27 p
(Grant NAG3-1232; RTOP 505-62-50)
(NASA-CR-195307; E-8714; NAS 1.26:195307) Avail: CASI HC A03/MF A01

This work investigates the effects of actuator saturation in multi-input, multi-output (MIMO) control systems. The adverse system behavior introduced by the saturation nonlinearity is viewed here as resulting from two mechanisms: controller windup - a problem caused by the discrepancy between the limited actuator commands and the corresponding control signals, and directionality - the problem of how to use nonlimited actuators when a limited condition exists. The tracking mode and Hanus methods are two common strategies for dealing with the windup problem. It is seen that while these methods alleviate windup, performance problems remain due to plant directionality. Though high gain conventional antiwindup as well as more general linear methods have the potential to address both windup and directionality, no systematic design method for these schemes has emerged; most approaches used in practice are application driven. An alternative method of addressing the directionality problem is presented which involves the introduction of a control direction preserving nonlinearity to the Hanus antiwindup system. A nonlinearity is subsequently proposed which reduces the conservation inherent in the former direction-preserving approach, improving performance. The concept of multivariable sensitivity is seen to play a key role in the success of the new method.

Motion-dependent magnetic forces are the key elements in the study of magnetically levitated vehicle (maglev) system dynamics. In the past, most maglev-system designs were based on a quasisteady-motion theory of magnetic forces. This report presents an experimental and analytical study that will enhance our understanding of the role of unsteady-motion-dependent magnetic forces and demonstrate an experimental technique that can be used to measure those unsteady magnetic forces directly. The experimental technique provides a useful tool to measure motion-dependent magnetic forces for the prediction and control of maglev systems. DOE

SIMULTANEOUS PRESSURE MEASUREMENT AND HIGH-SPEED PHOTOGRAPHY STUDY OF CAVITATION IN A DYNAMICALLY LOADED JOURNAL BEARING
D. C. Sun (State Univ. of New York, Binghamton.), David E. Brewe (Army Research Lab., Cleveland, OH.), and Philip B. Abel Feb. 1994 17 p Presented at the ASME/STLE Tribology Conference, San Diego, CA, 18-21 Oct. 1992; sponsored by ASME and the Society of Tribologists and Lubrication Engineers
(DA Proj. 1L1-61102-AH-45; RTOP 505-63-5A)
(NASA-TM-106456; E-6834; NAS 1.15:106456; ARL-TR-10) Avail: CASI HC A03/MF A01

Cavitation of the oil film in a dynamically loaded journal bearing was studied using high-speed photography and pressure measurement simultaneously. Comparison of the visual and pressure data provided considerable insight into the occurrence and nonoccurrence of cavitation. It was found that (1) for the submerged journal bearing, cavitation typically occurred in the form of one bubble with the pressure in the cavitation bubble close to the absolute zero; and (2) for cavitation-producing operating conditions, cavitation did not always occur; with the oil film then supporting a tensile stress. MANUAL FOR AUTOMATIC GENERATION OF FINITE ELEMENT MODELS OF SPIRAL BEVEL GEARS IN MESH Final Report
G. D. Bibel, S. Reddy, and A. Kumar Apr. 1994 58 p
(Grant NAG3-1476; DA Proj. 1L1-62211-A-47-A; RTOP 505-62-36)
(NASA-CR-191009; E-8671; NAS 1.26:191009; ARL-CR-121) Avail: CASI HC A04/MF A01

The goal of this research is to develop computer programs that generate finite element models suitable for doing 3D contact analysis of faced milled spiral bevel gears in mesh. A pinion tooth and a gear tooth are created and put in mesh. There are two programs: Points.f and Pat.f to perform the analysis. Points.f is based on the equation of meshing for spiral bevel gears. It uses machine tool settings to solve for an N x M mesh of points on the four surfaces, pinion concave and convex, and gear concave and convex. Points.f creates the file POINTS.OUT, an ASCI file containing N x M points for each surface. (N is the number of node points along the length of the tooth, and M is nodes along the height.) Pat.f reads POINTS.OUT and creates the file tl.out. Tl.out is a series of PATRAN input commands. In addition to the mesh density on the tooth face, additional user specified variables are the number of finite elements through the thickness, and the number of finite elements along the tooth full fillet. A full fillet is assumed to exist for both the pinion and gear. Author

FEED-FORWARD CONTROL OF GEAR MESH VIBRATION USING PIEZOELECTRIC ACTUATORS
Gerald T. Montague (NYMA, Inc., Brook Park, OH.), Albert F. Kascak, Alan Palazzolo, Daniel Manchala, and Erwin Thomas May 1994 21 p
(DA Proj. 1L1-61102-AH-45; RTOP 505-62-06; RTOP 505-63-5B)
(NASA-TM-106366; E-8168; NAS 1.15:106366; ARL-TR-416) Avail: CASI HC A03/MF A01

This paper presents a novel means for suppressing gear mesh-related vibrations. The key components in this approach are piezoelectric actuators and a high-frequency, analog feed-forward controller. Test results are presented and show up to a 70-percent reduction in gear mesh acceleration and vibration control up to 4500 Hz. The principle of the approach is explained by an analysis of a harmonically excited, general linear vibratory system. Author

A PROCEDURE FOR 3-D CONTACT STRESS ANALYSIS OF SPIRAL BEVEL GEARS Final Report
A. Kumar and G. Bibel Mar. 1994 87 p
(Grant NAG3-1476; DA Proj. 1L1-62211-A-47-A; RTOP 505-62-10)
(NASA-CR-194472; E-8613; NAS 1.26:194472; ARL-CR-72) Avail: CASI HC A05/MF A01

Contact stress distribution of spiral bevel gears using nonlinear finite element static analysis is presented. Procedures have been developed to solve the nonlinear equations that identify the gear and pinion surface coordinates based on the kinematics of the cutting process and orientate the pinion and the gear in space to mesh with each other. Contact is simulated by connecting GAP elements along the intersection of a line from each pinion point (parallel to the normal at the contact point) with the gear surface. A three dimensional model with four gear teeth and three pinion teeth is used to determine the contact stresses at two different contact positions in a spiral bevel gearset. A summary of the elliptical contact stress distribution is given. This information will be helpful to helicopter and aircraft transmission designers who need to minimize weight of the transmission and maximize reliability. Author (revised)

SPUR, HELICAL, AND SPIRAL BEVEL TRANSMISSION LIFE MODELING
Michael Savage (Akron Univ., OH.), Kelly L. Rubadeux (Akron Univ., OH.), Harold H. Coe, and John J. Coy Apr. 1994 13 p Proposed for presentation at the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; sponsored by AIAA, SAE, ASME, and ASEE
(DA Proj. 1L1-62211-A-47-A; RTOP 505-62-10)
(NASA-TM-106552; E-8707; NAS 1.15:106552; ARL-TR-390; AIAA Paper 94-3079) Avail: CASI HC A03/MF A01

A computer program, TLIFE, which estimates the life, dynamic capacity, and reliability of aircraft transmissions, is presented. The program enables comparisons of transmission service life at the design stage for optimization. A variety of transmissions may be analyzed including: spur, helical, and spiral bevel reductions as well as series combinations of these reductions. The basic spur and helical reductions include: single mesh, compound, and parallel path plus revert star and planetary gear trains. A variety of straddle and overhung bearing configurations on the gear shafts are possible as is the use of a ring gear for the output. The spiral bevel reductions include single and dual input drives with arbitrary shaft angles. The program is written in FORTRAN 77 and has been executed both in the personal computer DOS environment and on UNIX workstations. The analysis may be performed in either the SI metric or the English inch system of units. The reliability and life analysis is based on the two-parameter Weibull distribution lives of the component gears and bearings. The program output file describes the overall transmission and each constituent transmission, its components, and their locations, capacities, and loads. Primary output is the dynamic capacity and 90-percent reliability and mean lives of the unit transmissions and the overall system which can be used to estimate service overhaul frequency requirements. Two examples are presented to illustrate the information available for single element and series transmissions. Author

TORQUE CHARACTERISTICS OF SOLID LUBRICATED PRECISION BEARINGS DURING OSCILLATORY MOTION
Reinhold Bauer and Paul D. Fleischauer 31 Jan. 1994 36 p
(Contract F04701-93-C-0094)
(AD-A278133; TR-93(3935)-11; SMC-TR-94-13) Avail: CASI HC A03/MF A01

MoS2 sputter-coated as well as uncoated (bare) angular-contact ball bearings were tested with various cage materials in a low-speed regime. Various self-lubricating polymers either neat or with additives and metallic cages were tested. The emphasis of this paper is to report on significant

torque increases torque bumps observed during non-ball overlap, oscillatory motion for some race/cage combinations. In some race/cage combinations torque bumps can be minimized by proper run-in. No attempt was made to run the bearings to failure, although certain race/cage combinations did in fact fail before the end of test. DTIC

A REVIEW OF WELDMENT FAILURE MODES AND WELDABILITY TESTING METHODS Final Report
George Young Jan. 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278096; ARCCB-TR-94003) Avail: CASI HC A03

An engineering study was conducted that reviewed typical weldment failure modes and the types of weldability test procedures currently used to predict behavioral response of a material that is to be welded. In comparing the design effectiveness of these tests, each has certain inherent technical advantage/disadvantages associated with it. The tests, if used appropriately, can save untold time and costs associated with poorly welded structures/components that fail in service prematurely. They are divided into two major categories, direct and indirect, related to the test methodology or procedure used to generate results. Specifically, direct tests make use of actual weldments, while indirect tests utilize basic metallurgical principles to predict weld behavior. From this study, it should be apparent that determining what the most appropriate weldability test procedure is for obtaining useful results for a given situation is critical to the success of that test. EVALUATION OF NONDESTRUCTIVE INSPECTION TECHNIQUES FOR QUALITY CONTROL OF ALUMINA-CERAMIC HOUSING COMPONENTS Final Report
R. R. Kurkchubasche, R. P. Johnson, and J. D. Stachiw Sep. 1993 75 p
(NR Proj. SO3-97)
(AD-A276220; NCCOSC/RDT/E-TR-1588) Avail: CASI HC A04/MF A01

Alumina-ceramic pressure housings have been shown to be feasible and cost-effective alternatives to housings made from more traditional materials such as steel, titanium, or aluminum. The high specific compressive strength, and high specific elastic modulus of alumina ceramic allow engineers to design pressure housings having weight-to-displacement ratios lower than 0.60 for a service depth of 20,000 feet while remaining neutrally buoyant. Titanium housings designed to the same requirements have weight-to-displacement ratios in excess of 0.85. Although the difference may, at first glance, seem negligible, it accounts for a tripling of the housing payload weight capacity when alumina ceramic is substituted for titanium. The transition of alumina-ceramic pressure housing components from the developmental stage to the operational environment brings on the requirement for the capability of nondestructively inspecting these components for gross fabrication flaws and for in-service damage which may have occurred. Various radiographic and ultrasonic inspection methods are evaluated and compared based on their ability to detect defects, determine defect location, and characterize defect size and shape in large alumina-ceramic components used for deep submergence pressure housing applications. Recommendations based on the findings of the study are made for the nondestructive inspection of alumina-ceramic components. DTIC

EDDAKS (Event Driven Data Acquisition Kernel System), for the quality control of products created in industrial production processes, is proposed. It is capable of acquiring information about discrete event systems by synchronizing to them via the events. EDDAKS consists of EdObjects, forming a hierarchy, which react to EdEvents, and perform processing operations on messages. The hierarchy of EdObjects consists (from bottom up) of the Sensor, the Phase, the Extracter, the Dynamic Spreadsheet, and EDDAKS itself. The first three levels contribute to building the internal representation: a state vector characterizing a product in the course of production. The Dynamic Spreadsheet, is a processing structure that can be parameterized, used to perform calculations on a set of internal representations in order to deliver the external representation to the user. A system intended for quality control of the products delivered by a concrete production plant was generated by EDDAKS and used to validate. Processing methods using the multilayer perceptron model were considered. Two contributions aimed at improving the performance of this network are proposed. One consists of implanting a conjugate gradient method. The effectiveness of this method depends on the determination of an optimum gradient step that is efficiently calculated by a linear search using a secant algorithm. The other is intended to reduce the connectivity of the network by adapting it to the problem to be solved. It consists of identifying links having little or no activity and destroying them. This activity is determined by evaluating the covariance between each of the inputs of a cell and its output. An experiment in which nonlinear prediction is applied to a civil engineering problem is described. ESA

ULTRASONIC CHARACTERIZATION OF DAMAGE IN A SIMULATED CF-18 COMPOSITE STRUCTURE
K. I. McRae, R. D. Finlayson, W. R. Sturrock, and D. S. Liesch Feb. 1993 32 p
(DREP-LN-93-26; DSIS-94-01061; CTN-94-61219) Avail: CASI HC A03/MF A01

A simulated CF-18 aircraft door component was constructed and subjected to treatment during manufacturing with the object of inducing damage in the composite material in a known and well-defined manner. The simulated component was then sent to participants in a nondestructive evaluation study. Results are reported for tests conducted with a scanning apparatus and data acquisition system which consisted of three components: ultrasonic transducer and scanner comprising a two-axis scanning frame to which a modified commercial transducer was attached; an acquisition system for ultrasonic data known as Signal Processing Ultrasonic Device (SPUD); and a data analysis and display system (DETECT/NDE) specifically designed to manipulate large three dimensional ultrasonic data sets. A series of five large-area scans was performed, each scan about 52 cm square. A total of eight regions of interest were identified for a more detailed analysis of the delamination damage, seven detailed scans covering a 13-cm square and one covering a 20.8-cm square. It was often possible to identify the probable source of the damage as that resulting from impact or caused by overloading of fasteners. Flaws of all significant dimensions were located and fully characterized using the ultrasonic procedure. Author (CISTI)

This technology assessment report is the result of compilation, review, and assessment of information and data concerning the development and use of NDE/T as applied to advanced composites that may be used in the CAV (Composite Armored Vehicle) ATD (Advanced Technology

Demonstrator) Program. This information has been gained from both published literature and as well as work in progress. It includes the results of a detailed bibliographic search using all the data bases held within the Defense Technical Information Center, supplemented wherever possible by other data bases. In addition, direct contacts and academic, industrial, and government research and development centers and applications laboratories were made. Discussions and recommendations contained in this report focus on the current state-of-the-art of composite NDE/T technologies and their capabilities and limitations for both the classical post process and real-time in-process inspection techniques. Furthermore, this effort includes an assessment of future developments and research trends including a projected time line. DTIC

MANAGEMENT OF GOVERNMENT QUALITY ASSURANCE FUNCTIONS FOR NASA CONTRACTS
Apr. 1993 66 p
(NHB-5300.4(2B-2); NAS 1.18:5300.4(2B-2)) Avail: CASI HC A04/MF A01

This handbook sets forth requirements for NASA direction and management of government quality assurance functions performed for NASA contracts and is applicable to all NASA installations. These requirements will standardize management to provide the minimum oversight and effective use of resources. This handbook implements Federal Acquisition Regulation (FAR) Part 46, NASA FAR Supplement 18-46, Quality Assurance, and NMI 7410.1. Achievement of established quality and reliability goals at all levels is essential to the success of NASA programs. Active participation by NASA and other agency quality assurance personnel in all phases of contract operations, including precontract activity, will assist in the economic and timely achievement of program results. This involves broad participation in design, development, procurement, inspection, testing, and preventive and corrective actions. Consequently, government, as well as industry, must place strong emphasis on the accomplishment of all functions having a significant bearing on quality and reliability from program initiation through end-use of supplies and services produced. For purposes of implementing NASA and other agency agreements, and to provide for uniformity and consistency, the terminology and definitions prescribed herein and in a future handbook shall be utilized for all NASA quality assurance delegations and subsequent redelegations. DIFFERENTIAL PHASE ACOUSTIC MICROSCOPE FOR MICRO-NDE Final Report
David D. Waters, T. L. Pusateri, and S. R. Huang May 1992 108 p Revised
(Contract NAS1-19099; SBIR-04.09-6425A; RTOP 324-02-00)
(NASA-CR-189617; NAS 1.26:189617; BIR-2380) Avail: CASI HC A06/MF A02

A differential phase scanning acoustic microscope (DP-SAM) was developed, fabricated, and tested in this project. This includes the acoustic lens and transducers, driving and receiving electronics, scanning stage, scanning software, and display software. This DP-SAM can produce mechanically raster-scanned acoustic microscopic images of differential phase, differential amplitude, or amplitude of the time gated returned echoes of the samples. The differential phase and differential amplitude images provide better image contrast over the conventional amplitude images. A specially designed miniature dual beam lens was used to form two foci to obtain the differential phase and amplitude information of the echoes. High image resolution (1 micron) was achieved by applying high frequency (around 1 GHz) acoustic signals to the samples and placing two foci close to each other (1 micron). Tone burst was used in this system to obtain a good estimation of the phase differences between echoes from the two adjacent foci. The system can also be used to extract the V(z) acoustic signature. Since two acoustic beams and four receiving modes are available, there are 12 possible combinations to produce an image or a V(z) scan. This provides a unique feature of this system that none of the existing acoustic microscopic systems can provide for the micro-nondestructive evaluation applications. The entire system, including the lens, electronics, and scanning control software, has made a competitive industrial product for nondestructive material inspection and evaluation and has attracted interest from existing acoustic microscope manufacturers. HIERARCHICAL MODELING FOR RELIABILITY ANALYSIS USING MARKOV MODELS B.S./M.S. Thesis - MIT
Arturo Fagundo May 1994 116 p
(Contract NAS9-18426)
(NASA-CR-188288; NAS 1.26:188288; CSDL-T-1220) Avail: CASI HC A06/MF A02

Markov models represent an extremely attractive tool for the reliability analysis of many systems. However, Markov model state space grows exponentially with the number of components in a given system. Thus, for very large systems Markov modeling techniques alone become intractable in both memory and CPU time. Often a particular subsystem can be found within some larger system where the dependence of the larger system on the subsystem is of a particularly simple form. This simple dependence can be used to decompose such a system into one or more subsystems. A hierarchical technique is presented which can be used to evaluate these subsystems in such a way that their reliabilities can be combined to obtain the reliability for the full system. This hierarchical approach is unique in that it allows the subsystem model to pass multiple aggregate state information to the higher level model, allowing more general systems to be evaluated. Guidelines are developed to assist in the system decomposition. An appropriate method for determining subsystem reliability is also developed. This method gives rise to some interesting numerical issues. Numerical error due to roundoff and integration are discussed at length. Once a decomposition is chosen, the remaining analysis is straightforward but tedious. However, an approach is developed for simplifying the recombination of subsystem reliabilities. Finally, a real world system is used to illustrate the use of this technique in a more practical context. Author

EVALUATION OF PYROLYSIS AND ARC TRACKING ON CANDIDATE WIRE INSULATION DESIGNS FOR SPACE APPLICATIONS Final Report
Thomas J. Stueber, Ahmad Hammoud, Mark W. Stavnes, and Kenneth Hrovat May 1994 7 p
(Contract NAS3-27186; RTOP 323-57-4A)
(NASA-CR-195332; E-8849; NAS 1.26:195332) Avail: CASI HC A02/MF A01

Polyimide wire insulation has been found to be vulnerable to pyrolization and arc tracking due to momentary short circuit arcing events. This report compares arc tracking susceptibility of candidate insulation configurations for space wiring applications. The insulation types studied in this report were gauge 20 (0.81 mm dia.) hybrid wiring constructions using polyimide, tetrafluoroethylene (TFE), cross-linked ethylene tetrafluoroethylene (XL-ETFE) and/or polytetrafluoroethylene (PTFE) insulations. These constructions were manufactured according to military wiring standards for aerospace applications. Arc track testing was conducted under DC bias and vacuum (10(exp -6) torr). The tests were conducted to compare the various insulation constructions in terms of their resistance to arc tracking restrike. The results of the tests are presented. Author

IMPLEMENTING SOFTWARE SAFETY IN THE NASA ENVIRONMENT
Martha S. Wetherholt and Charles F. Radley May 1994 19 p Presented at the Safety Through Quality Conference, Old Windsor, England, 6-7 Jun. 1994; sponsored by the Real Time Associates, Ltd.
(Contract NAS3-26764; RTOP 323-88-03)
(NASA-TM-106597; E-8870; NAS 1.15:106597) Avail: CASI HC A03/MF A01

Until recently, NASA did not consider allowing computers total control

of flight systems. Human operators, via hardware, have constituted the ultimate safety control. In an attempt to reduce costs, NASA has come to rely more and more heavily on computers and software to control space missions. (For example, software is now planned to control most of the operational functions of the International Space Station.) Thus the need for systematic software safety programs has become crucial for mission success. Concurrent engineering principles dictate that safety should be designed into software up front, not tested into the software after the fact. 'Cost of Quality' studies have statistics and metrics to prove the value of building quality and safety into the development cycle. Unfortunately, most software engineers are not familiar with designing for safety, and most safety engineers are not software experts. Software written to specifications which have not been safety analyzed is a major source of computer related accidents. Safer software is achieved step by step throughout the system and software life cycle. It is a process that includes requirements definition, hazard analyses, formal software inspections, safety analyses, testing, and maintenance. The greatest emphasis is placed on clearly and completely defining system and software requirements, including safety and reliability requirements. Unfortunately, development and review of requirements are the weakest link in the process. While some of the more academic methods, e.g. mathematical models, may help bring about safer software, this paper proposes the use of currently approved software methodologies, and sound software and assurance practices to show how, to a large degree, safety can be designed into software from the start. NASA's approach today is to first conduct a preliminary system hazard analysis (PHA) during the concept and planning phase of a project. This determines the overall hazard potential of the system to be built. Shortly thereafter, as the system requirements are being defined, the second iteration of hazard analyses takes place, the systems hazard analysis (SHA). During the systems requirements phase, decisions are made as to what functions of the system will be the responsibility of software. This is the most critical time to affect the safety of the software. From this point, software safety analyses as well as software engineering practices are the main focus for assuring safe software. While many of the steps proposed in this paper seem like just sound engineering practices, they are the best technical and most cost effective means to assure safe software within a safe system. PSIDD: A POST-SCAN INTERACTIVE DATA DISPLAY SYSTEM FOR ULTRASONIC SCANS

Don J. Roth and Steven A. Szatmary Washington Nov. 1993 24 p Original contains color illustrations

(RTOP 510-01-50)

(NASA-TM-4545; E-8167; NAS 1.15:4545) Avail: CASI HC A03/MF A01; 10 functional color pages

An ultrasonic data display system was developed at NASA Lewis Research Center that allows the user to interactively examine digitized waveforms and processed information associated with any specific scan location of an ultrasonic contact scan. This information is displayed on a video display monitor and includes acquired time-domain waveforms, frequency-domain magnitude and phase spectra, and ultrasonic properties (pulse velocity, phase velocity, reflection coefficient, attenuation coefficient, attenuation coefficient error) as a function of frequency for a material. This report describes the system features and illustrates the system's usefulness for nondestructive materials characterization. Author

ACCELERATED RELIABILITY TESTING UTILIZING DESIGN OF EXPERIMENTS Report, May - Sep. 1993

Barry T. McKinney Dec. 1993 146 p

(AF Proj. 2338)

(AD-A277989; RL-TR-93-249) Avail: CASI HC A07/MF A02

This report documents a system-level Accelerated Reliability testing methodology. The method requires no specific assumptions of a Time-to-Failure distribution nor a stress/performance model. The methodology results in a multi-stress environmental test based on Design of Experiments, specifically a one-third fractional factorial design. The test data are modeled by the method of orthogonal polynomials. Although the data are collected in a high-stress environment, an operational performance estimate can established without extrapolating beyond the test data limits. DTIC

SPACE FLIGHT PRINTED WIRING BOARD MEASLING INVESTIGATION

Walter B. Thomas, III May 1994 18 p

(RTOP 312-00-00)

(NASA-TM-104602; Rept-94B00071; NAS 1.15:104602) Avail: CASI HC A03/MF A01

A flight printed wiring board (PWB) for a satellite project was observed to have a high incidence of measling. Other PWB's produced for the program by the same manufacturer did not exhibit the degree of measling as did the 'measle-prone' board. Measling susceptibility during hand soldering and measling effects on PWB insulation resistance were investigated for three production PWB's. Measling resistance was significantly different between the three boards: the 'worst' exhibited five times the number of measles as the 'best' board. 'Severe' measling (that which is likely to affect board reliability) did not exist on the 'best' board, even under extreme soldering conditions (399 degrees C for 12-15 sec.), whereas the 'worst' board showed an average of one 'severe' measle for every two pads under more normal soldering conditions (288-343 degrees C for 2-5 sec.). Both soldering time and temperature affected measling, with time having a slightly greater influence (2 percent versus 12 percent). Measling effects on PWB insulation resistance were inconclusive. These were evaluated by in situ resistance measurements on the same three boards at elevated temperature and humidity. The measured resistance for all three boards decreased for exposures greater than 50 degrees C and 50 percent relative humidity. The 'measle-prone' board showed a resistance decrease at only 25 degrees C and 50 percent relative humidity. However, no definitive difference was detected between measled and not-measled (control) samples. The boards evaluated were production boards, so the effect of interlayer traces connecting the plated-through holes was not controlled. It is likely the resistance measurements were over different volumes of PWB laminate, which would account for the widely varying resistances measured. Thermomechanical measurements on board laminate materials did not reveal any differences attributed to measling. Differences in glass transition temperature were significantly different when measured by DTA, but not by SDT. Laminate thermal expansion differences were significant for the 35 degrees C evaluations, but not for any higher temperatures. Author

MODEL UPDATING OF VIBRATING SYSTEMS BASED ON MEASURED OR CALCULATED FREQUENCY RESPONSE FUNCTIONS Thesis

Carl-Ove Kolmodin and Martin Spaang Mar. 1993 40 p Sponsored by Volvo AB, Goeteberg Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ISSN 0283-8338)

(CTH-E-93-03; ETN-94-95951) Avail: Issuing Activity (European Space Agency (ESA))

A method for updating analytical models using measured frequency response functions was investigated. The possibility of using measured data as input data is investigated using a vibrator isolator. A simple model

is used and the isolator properties are updated from dynamic measurements made on the isolator. The quality of the model and the need for an accurate theoretical model and high quality measurement data are discussed. The basic theory is presented and the completeness of measured coordinates are stressed. The use of this updating technique for the updating of finite element models are investigated. An exact theoretically derived with Euler-Bernoulli theory was used as input data for the updating. ESA

VIBRATION CONTROL AND DESIGN OF COMPOSITE CANTILEVERS TAKING INTO ACCOUNT STRUCTURAL UNCERTAINTIES AND DAMAGE Ph.D. Thesis
Donghoon Oh 1993 219 p
Avail: Univ. Microfilms Order No. DA9323788

Within this work a study of the vibrations of laminated composite cantilevers exhibiting structural uncertainties and damage is accomplished. The study is performed within both the Classical Lamination (CLT) and the First-order Transverse Shear Deformation Theories (FSDT). Upon comparing the natural frequencies and mode shapes obtained by both theories, the effects of transverse shear deformation will be emphasized. Other nonclassical effects, such as the bending-twist coupling and the warping restraint on the cantilevered structure, are also considered. Structural tailoring and optimization are implemented as passive techniques of vibration control. To deal with structural uncertainties, a probabilistic discretization technique for the governing system is developed. Statistical properties of natural frequencies are obtained by means of a second-moment method and a first-order perturbation technique. Structural tailoring is reconsidered to reduce the sensitivity of the dynamic behavior to parameter uncertainties. Next, the damage effect on the structure is considered in the design process. As a result, the problem of the robustness of structures in the presence of damage is addressed. This work also deals with the active feedback control of cantilevered structure systems. An efficient control technique for continuous structures, namely modal control, is adopted, and the control gain is obtained by an optimal control law. The comparison of controlled and uncontrolled dynamic responses is made between two models based on CLT and FSDT with emphasis on the influence played by transverse shear deformation and warping restraint. Dissert. Abstr.

DEFORMATION AND RUPTURE OF CYLINDRICAL SHELLS UNDER DYNAMIC LOADING Ph.D. Thesis
Michelle S. HooFatt 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

The dynamic plastic response and failure of unstiffened and ring stiffened cylindrical shells subjected to dynamic loads were studied. The proposed solution methodology, based on a simple computational model of the shell and the concept of equivalence parameters, incorporated two main load-resisting mechanisms in the shell stretching in the longitudinal direction and bending in the circumferential direction. From this method, the complicated two-dimensional cylindrical shell problem was reduced to a one-dimensional problem of a string on-foundation. In particular, the magnitude of the transient and final shape of the transverse deflections of the shell undergoing impact and explosive-type loading were predicted. In order to predict shell failure, the solution for the transient deflection was coupled with a simple fracture criterion--the critical strain to rupture. Both exact and approximate solutions for the impact and impulsive loading of the unstiffened shell were compared and gave similar results for high velocity impact and impulsive loading. In the ring-stiffened shell, the overall deflection profile was shown to consist of both a global and local (between stiffeners) deflection field thereby revealing a complex interplay between the stiffener and the bay. Furthermore, a parametric study on the stiffened shell showed that string-on-foundation model for which ring-stiffeners are represented by lumped masses and springs is a promising method of analyzing the structure. EFFECT OF VIBRATORY STRESS RELIEF DURING WELDING OF THICK STAINLESS STEEL PLATE
S. Spooner, S. A. David, X. L. Wang, C. R. Hubbard, T. M. Holden, and J. H. Root 1993 5 p Presented at the American Welding Society International Conference on Modeling and Control of Joining Processes, Orlando, FL, 8-10 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-006557; CONF-931234-6) Avail: CASI HC A01/MF A01

Residual strains were measured in two welded 25-mm thick plates of type 304 stainless steel by the neutron diffraction technique. The filler metal employed to weld these plates was type 308 stainless steel. One of the two welds was prepared without any vibratory stress relief treatment and the other was vibrated at a frequency below the resonant condition which gives a fraction the resonant amplitude during welding. In both plates the largest residual stress component found in the heat affected zone and in the base metal is along the fusion joint (longitudinal) and is found at the boundary between the weld zone and the heat affected zone. This longitudinal component is 300 +/- 50 MPa in tension. The associated normal stress was close to zero and the transverse stress was 80 +/- 50 MPa. Variations in residual stresses with thickness through the base metal plate were small. The treated plate and untreated plate showed nearly identical patterns of stress distribution. Differences in the measured stresses between the vibratory-stress-relief treated and the untreated plates fall within the error bars of the stress determination in these particular 25 mm thick 300-type stainless steel plates. TEARING RESISTANCE OF A THIN SHELL AGAINST PROJECTILE PENETRATION: MATERIAL PROPERTY EFFECTS
K. V. Trinh Jan. 1994 28 p
(Contract DE-AC04-76DR-00789)
(DE94-007466; SAND-93-8221) Avail: CASI HC A03/MF A01

This report presents results from a series of finite element analyses performed to study material effects on the tearing resistance of a thin shell subjected to projectile penetration. These analyses simulated a round, slender projectile impacting the top center of a metallic cylindrical shell at high speed. We varied eight selected shell material properties systematically using an L18 matrix (design of experiment technique). From the results, we determined effects of the eight properties on the minimum projectile velocity required to penetrate the shell. The material properties examined here included: yield strength, hardening and recovery characteristics, heat coefficient, initial porosity, and damage exponent (a void growth parameter). The DYNA2D finite element code along with the Sandia plasticity/damage model for ductile metals were used in the analyses. DOE

CONSIDERING TIES ELASTICITIES IN HIGH FREQUENCY RAIL DYNAMICS [DIE BERUECKSICHTIGUNG VON SCHWELLENELASTIZITAETEN IN DER HOCHFREQUENTEN GLEISDYNAMIK]
K. Knothe, N. Ilias, M. Goetz, and B. Ripke May 1993 22 p In GERMAN
(ILR-Mitt-281(1993); ETN-94-95743) Avail: CASI HC A03/MF A01

The eigenfrequencies of elastic railroad ties are experimentally and numerically determined. The eigenfrequencies were experimentally obtained for vertical and lateral eigenoscillations shapes. A finite element program, which contains interpolation hermitian polynomials, was used for calculating eigenfrequencies; bending and shear stiffnesses were taken into consideration and the coupling between flexion and torsion was neglected. The results were compared with data obtained for rigid ties. An approximation formula for eigenfrequency calculation of ties, based on the assumption of a beam with constant stiffness and subjected to shear deformation and torsional inertia, was given. A model which takes into account the elastic properties of ties was developed for calculating the compliance of rails in the frequency area. From the results it can be deduced that elastic calculations for ties are only necessary for frequencies lower than 200 Hz. ESA

CONTRIBUTIONS TO THE VALIDATION OF THE CJS MODEL FOR GRANULAR MATERIALS Ph.D. Thesis [CONTRIBUTIONS A LA VALIDATION DU MODELE CJS POUR LES MATERIAUX GRANULAIRES]
Khadija Elamrani 1992 167 p In FRENCH Limited Reproducibility:

More than 20% of this document may be affected by microfiche quality
(ECL-92-56; ETN-94-95908) Avail: CASI HC A08

Behavior model validation in the field of geotechnics is addressed, with the objective of showing the advantages and limits of the CJS (Cambou Jafari Sidoroff) behavior model for granular materials. Several levels are addressed: theoretical analysis of the CJS model to reveal consistence and first capacities; shaping (followed by validation by confrontation with other programs) of a computation code by finite elements (FINITEL) to integrate this model and prepare it for complex applications; validation of the code/model structure thus constituted by comparing its results to those of experiments in the case of nonhomogeneous (superficial foundations) problems. MODELING OF FRACTURE AND DAMAGE IN QUASIBRITTLE MATERIALS Ph.D. Thesis
Milan Jirasek 1993 254 p
Avail: Univ. Microfilms Order No. DA9327222

The dissertation presents several mathematical models useful for the simulation of fracture and damage propagation in quasi-brittle materials, which are characterized by the development of a large nonlinear process zone prior to failure. The simplest one is the R-curve model based on the replacement of the nonlinear fracture process zone by an equivalent linear elastic crack with a variable resistance against crack propagation. This approach is generalized by taking into account the effect of the loading rate. The emphasis is on the static loading rates rather than the dynamic ones, and creep in the bulk of the specimen is incorporated into the mathematical description. Another important class of models is based on the representation of a mechanical system by an assembly of interacting particles. A dynamic particle model is developed for the simulation of fracture of large sea ice floes during their impact on obstacles such as platforms or artificial islands. It is demonstrated that this model is capable of producing realistic results in terms of both the contact force history and the fracture pattern. Macroscopic fracture energy of random particle systems is studied as a function of the microscopic parameters using the size effect method. An effective numerical procedure for tracing a piecewise linear load-displacement curve is developed. The previously proposed continuum-based microplane model is carefully analyzed and shown to perform poorly in certain situations. The conditions under which the model gives unsatisfactory results are described and the reasons for the poor performance are explained. Modifications on the microscopic level do not remedy the situation and a macro-level modification is unavoidable. A promising concept of the revised version is advocated by presenting improvements of the behavior in several elementary situations. The dissertation is concluded by a localization analysis of a new concept of nonlocal averaging, strictly based on a micromechanically justified derivation. The analysis of the bifurcation at peak stress is followed by an incremental analysis of the post-peak behavior. It is shown that the new formulation preserves the essential properties of the original nonlocal approach and has some interesting added features. Dissert. Abstr.

CONTRIBUTION TO THE STUDY OF MULTIAXIAL FATIGUE UNDER PERIODIC OR RANDOM STRESSES Ph.D. Thesis [CONTRIBUTION A L'ETUDE DE LA FATIGUE MULTIAXIALE SOUS SOLLICITATIONS PERIODIQUES OU ALEATOIRES]
Jean-Louis Robert 1992 225 p In FRENCH
(ISAL-92-0004; ETN-94-95919) Avail: CASI HC A10/MF A03

A study aiming to give a random multiaxial fatigue life prediction method, by adapting to this problem long fatigue life criteria and Rainflow counting methods, is presented. Five 'classical' fatigue criteria for multiaxial and periodical stresses are analyzed. A criterion based upon the determination of the critical plane, experiencing the maximum damage evaluated with tangential and normal stresses on this plane, is proposed. The comparison between all criteria is made with 100 experimental tests collected in the literature. The criterion gives especially good predictions when principal stresses directions are fixed. Four rainflow counting methods are examined and a new one is proposed. Two ways of comparison are developed: rainflow cumulatives are modeled by a probability densities law and theoretical fatigue life predictions are calculated with either a linear or a nonlinear damage law. A method to calculate the constants of materials for these two approaches is described. It allows identical Woehler curves to be reproduced. Uniaxial loading histories measured on lorry components are used to compare these rainflow counting methods. A random multiaxial fatigue life prediction method is developed. Both counting variable and criterion proposed are based upon the tangential octahedric stress. The validation of the criterion is made by using experimental tests. The method is applied to loading histories and is satisfactory. ESA

METHODOLOGY FOR DAMAGE STUDY OF A TUBE-GRILL CONTACT Ph.D. Thesis [METHODOLOGIE POUR L'ETUDE DE L'ENDOMMAGEMENT D'UN CONTACT TUBE-GRILLE]
Jean-Marc Voisin 1992 109 p In FRENCH
(ECL-92-49; ETN-94-95911) Avail: CASI HC A06/MF A02

Research for the 'ideal material' for the tube-grill contact of a steam generator is presented. A test bench (shock and sliding movements) was created to approach real operating conditions leading to matter loss of the stressed pieces. Study of bonding and cracking led to the development of a test procedure which characterizes the behavior of different materials in small fretting stressed contact. Experimental study gave the following conclusions. At vibratory test level, geometrical singularities of contact must be avoided. This is essentially a design problem. A bore of greater hardness than the tube is prejudicial for a good joint-holding with regard to wear. At the bonding simulation level, the test, being of a more general character, can show the catastrophic risks of cracking. The behavior of the materials put in contact must not lead to strong local stresses, otherwise the cracks can initiate and propagate to the periphery of the contact by a fatigue mechanism. The reliability of the installation requires that the stresses be weak since crack presence can not be allowed. ESA

THERMAL-MECHANICAL FATIGUE CRACK GROWTH IN AIRCRAFT ENGINE MATERIALS Ph.D. Thesis
Yi Dai May 1993 353 p
(ISBN-0-315-86543-1; CTN-94-61209) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A thermal mechanical fatigue (TMF) testing rig was built which is capable of studying the fatigue behaviors of gas turbine engine materials under simultaneous changes of temperatures and strains or stress. An advance alternating current potential drop (ACPD) measurement system was also developed which is capable of performing on-line monitoring of fatigue crack initiation and growth in specimen testing under isothermal and TMF conditions. Fatigue crack initiation and short crack growth data were obtained for titanium alloy specimens designed with notch features associated with bolt holes of compressor discs. TMF data were also obtained for two titanium alloys used in aircraft engine components. Those data explained the material fatigue behavior encountered in full-scale component testing. A complete fractographic analysis was performed on the tested specimens enhancing the understanding of the fatigue crack growth mechanisms and helping to formulate an analytical crack growth model. The ACPD fatigue crack monitoring technique was applied to the low cycle fatigue testing of Pratt & Whitney 1480 monocrystalline nickel alloy. A completely automated, computer controlled test procedure was developed which could obtain crack initiation and growth data with greater speed, precision, and reliability than previous methods. POINT-CONTACT AND POINT-IMPACT DYNAMICS FOR MULTIBODY CHAINS M.S. Thesis
Ralph Rainer Jahn 1993 150 p
(ISBN-0-315-87056-7; CTN-94-61245) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Open multibody chains are used to model robotic manipulator arms. Point-contact and point-impact dynamics are simulated as they relate to multibody chains, with a view toward application to manipulator systems used in space. To make the simulation effort tractible, contact surfaces are modelled as points. This is of significance to many space applications where a large number of contact and impact situations deal with small contact areas such as contact with structures along edges and corners. A Newton-Euler approach is implemented in conjunction with the finite element

method to model the mass and flexibility properties of the robotic links. Rigid systems and flexible systems are considered separately. The necessary simulation dynamics for a multibody chain is given, followed by a description of the point-contact strategy for the respective system. Outlines of the point-impact solution algorithm for each respective system are also presented along with simulation results for various examples. Several important programming considerations are described along with the numerical procedures implemented in the simulators. CISTI

RANDOM VIBRATIONS OF COMPOSITE BEAMS AND PLATES Ph.D. Thesis
Ahmad Shehadeh Abdelnaser 1993 181 p
Avail: Univ. Microfilms Order No. DA9312867

In this study, a generalized modal approach is presented to solve more general vibration problems of composite beams and plates. The coupled systems of partial differential equations, representing the equations of motion, are uncoupled into modal equations by utilizing the eigenfunctions of the system and its adjoint. A method is presented to obtain these eigenfunctions for beams with arbitrary boundary conditions and for plates with Levy-type boundary conditions. The forced vibration solutions obtained by this method are then used to calculate the random response characteristics of beams and plates subjected to spatially and temporally correlated random loads. In the analysis of beams, both symmetric cross-ply and angle-ply configurations have been considered. In the symmetric cross-ply configuration with no torsional loads, of course, the warping effects are absent. The angle-ply case, however, includes torsion-warping effects and coupled bending-torsion motions. A simple displacement field is introduced to reflect warping in the third-order shear deformation theory. In the analysis of plates two configurations of the laminates have also been considered: symmetric cross-ply and antisymmetric angle-ply. At this time, these are the only two configurations which can be solved by the closed-form modal analysis approach for the Levy-type boundary conditions. In both cases of the beams and plates, the numerical results with and without shear deformations are obtained and compared. The result for no shear deformation theory are obtained with the classical lamination theory. The results have also been obtained for the first-order shear deformation theory with a somewhat simpler displacement field which has been commonly used in the past. The numerical results are obtained for the global response quantities such as frequencies, displacements, and crossing rates as well as for the local response quantities such as normal and shear stresses across a cross section. The numerical results obtained with various deformation theories for the frequencies as well as response quantities are compared to evaluate the effect of the shear deformations. For thicker and rigid beams and plates, one observes large differences in the frequencies and responses obtained with (the first and third-order shear deformation theories) and without consideration of shear deformations (classical theory). For the frequencies and global responses, both the first and third-order theories give about the same results. Dissert. Abstr.

FUTUREPATH 3 (Videotape)
Oct. 1989 Videotape: 28 min. 55 sec. playing time, in color, with sound
(NASA-TM-109762; NONP-VT-94-9962) Avail: CASI VHS A01/BETA A22

The story of research and technology at NASA Lewis Research Center's Structures Division is presented. The job and designs of the Structures Division needed for flight propulsion is described including structural mechanics, structural dynamics, fatigue, and fracture. The video briefly explains why properties of metals used in structural mechanics need to be tested. Examples of tests and simulations used in structural dynamics (bodies in motion) are briefly described. Destructive and non-destructive fatigue/fracture analysis is also described. The arc sprayed monotape (a composite material) is explained, as are the programs in which monotape plays a roll. Finally, the National Aero-Space Plane (NASP or x-30) is introduced, including the material development and metal matrix as well as how NASP will reduce costs for NASA. CASI

ACCEPTANCE CRITERIA FOR WELD DEFECTS IN ALUMINIUM WELDMENTS
M. Hval 4 Aug. 1993 56 p Sponsored by Nordisk Industrifond
(PB94-138575; STF20-A93124) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report demonstrates the use of fracture mechanics to determine the significance of crack-like defects in aluminium weldments. In order to do so, fracture toughness data of 25 and 50 mm aluminum weld were determined. These results showed a large variation in the fracture toughness properties of the weldment, where the most critical zones were the fusion line and the hardness minimum of the HAZ. The fracture assessment was verified by comparing the results with four wide plate tests. The results of the defect assessment were dependent on the tensile input data for the weldments. For safe predictions it is proposed to use tensile input data for the average of the base material and the HAZ properties. On basis of the results simple defect acceptance criteria were determined for the weldments. NTIS

FEASIBILITY STUDY OF COLD EXPANSION PROCESSES MODELLING Final Report
Marie Bernard, Bui-Quoc Thang, Denis Julien, and Sylvain Forgues Mar. 1993 258 p
(DSIS-94-01186; CTN-94-61216) Avail: CASI HC A12/MF A03

A comprehensive review is presented of the cold expansion techniques currently used for the improvement of fatigue strength of fastened joints. Two common practices of generating residual stress fields responsible for increasing fatigue life are cold working of the open hole before fastener installation and interference fit fastener systems. Most of the materials studied were aluminum, and experimental work has shown that the benefits of cold working on fatigue life enhancement were substantial in some cases, particularly in the high cycle fatigue region. The performance of cold working depends on several parameters, the most influential being the material characteristics, degree of cold working, and remote applied stress. Analytical work characterizing cold working in order to establish the residual stress distribution uses several simplified assumptions, and analytical results may sometimes be unrealistic compared to results from experiments or finite element methods. Life prediction methods for cold worked materials, relaxation of the compressive residual stress during cycling, and nondestructive examination methods applied to cold working problems are also summarized. CRACKING INDUCED IN SMALL FRETTING: APPLICATION TO THE CASE OF AERONAUTICAL ALUMINUM ALLOYS Ph.D. Thesis [FISSURATION INDUITE EN PETITS DEBATTEMENTS: APPLICATION AU CAS D'ALLIAGES D'ALUMINIUM AERONAUTIQUES]
Zhong Rong Zhou 1992 164 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ECL-92-50; ETN-94-95906) Avail: CASI HC A08

Work aimed at defining bases for justifying the resistance to fretting of aluminum alloys used in aeronautics is presented. The friction characteristics of woodchips obtained for various experimental configurations are presented. The very notion of fretting resistance is stripped of sense since intrinsic properties of susceptible materials do not exist to describe the very different experimental configurations. The use of fretting maps which can separate the local stress that the first bodies support in terms of 'overcharge' or 'overdeformation' and derive the various responses of the material is proposed. The dynamics of the phenomenon regarding cracking are considered. By this response mode, the various alloys can be better separated. The introduction of these maps, and in particular the separation of 'local stress' maps and 'material response,' appears susceptible to strongly modify the behavior of users confronted with fretting problems, identification of them, and choice of remedies. Expected developments are discussed. In a nonclassical fashion, the study results in the proposal of a characterization test called static fretting fatigue, of which first results give hope for better account to be taken of the combined effect of loads related to contact or unrelated to contact. THE FINITE ELEMENT METHOD WITH ASYMPTOTIC SELF-SIMILAR SOLUTIONS Ph.D. Thesis
Marvin Luke 1993 161 p
Avail: Univ. Microfilms Order No. DA9326385

The application of self-similar solutions of the second kind as FEM special elements was examined. Self-similar solutions of the second kind are solutions to degenerate problems in physics where solution unknowns appear as exponents along with simple coefficients. They are of special interest because they represent the asymptotic solution for a wide class of non-degenerate initial conditions. In these problems the existence of an asymptotic solution is known, but the exact solution form is unknown. Self-similar solutions arise for two distinct classes of problems: (1) time-dependent point-source problems in which the solution is valid far away from the initial source, and (2) boundary layer type problems where the solution is valid in a small region where large changes occur. A finite element method is constructed that uses these asymptotic self-similar solutions. Two examples are solved. The first concerns a nonlinear time-dependent heat equation where the specific heat of the medium depends on whether it is heating or cooling. A self similar solution of the second kind is used as the solution representation for an infinite element. Unlike existing infinite element formulations the developed infinite element exhibits correct spatial and time asymptotic behavior. The interior region contains standard finite elements where the generalized trapezoidal method is used for time integration. An incomplete field method approximately enforces continuity of the solution both spatially and as a function of time at the element boundary interface. The results are compared with standard methods and found to be superior. The second example concerns an ordinary differential equation with a rapidly oscillating solution near a boundary. A special element is constructed to represent the solution in this region. This is coupled with hierarchical finite elements on the rest of the domain. Excellent results are achieved. Potential applications of self-similar solutions of the second kind in the finite element method are discussed. Dissert. Abstr.

(ISBN-0-315-86561-X; CTN-94-61213) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Cyclic tensile fatigue and compression fatigue were studied in 3-mole-percent yttria stabilized tetragonal zirconia polycrystals (3Y-TZP) and zirconia toughened alumina (ZTA) subjected to stress induced transformation. Clear striation-like dark bands separated by larger bright zones were observed in the tensile fatigue crack propagation of 3Y-TZP precracked specimens. The dark bands corresponded to matching depressions on the two opposite fractured surfaces and to regions of smaller amounts of transformation as confirmed by Raman spectroscopy. Hysteresis loops from a strain gauge placed at the fatigue crack tip of 3Y-TZP showed that fatigue crack propagation in a single cycle occurred in three stages: slow, very rapid, and slow propagation. The rapid propagation was always associated with presence of visible striations on the fatigue fracture surface and was triggered by a small amount of unloading in a load cycle. Fatigue resistance increased with increased stress intensity factor, a phenomenon believed to result from a transformation toughening effect. Fatigue crack propagation retardation was observed after a sustained load cycling, and fatigue crack propagation acceleration was observed during minor cycling. Explanations are suggested for both effects. Formation of four different zones on compression fatigue fracture surfaces is also explained.

VIBRATIONAL AND ACOUSTIC RESPONSE OF RIBBED PLATES Ph.D. Thesis
Ten-Bin Juang 1993 231 p
Avail: Univ. Microfilms Order No. DA9321175

A self-consistent mathematical formulation, using the Fourier transform method and a direct Gaussian numerical integration scheme, is developed and verified for analysis of both vibrational and acoustic responses of infinite submerged ribbed plates. Further steps developed from standard theories make structural intensity, acoustic intensity, and acoustic power calculations possible in the nearfield and farfield and are demonstrated in this work. The direct numerical integration scheme adopted to obtain responses has proved to be straightforward and reliable. Although the double integration expression in some responses makes the technique infeasible, a practical way to overcome that difficulty is demonstrated using a standard branch-cut integration to eliminate one integration step analytically. The model and numerical scheme readily allow investigation of additional interesting topics, like the passband and stopband characteristic and the mode localization phenomenon that are observed in ribbed structures. Furthermore, an extension to comprehension of the mechanisms that generate the mode localization phenomenon on disordered structures has been realized. A secondary effort examines natural modes of vibration and acoustic radiation for finite stiffened multiple-span beams with the efficient transfer matrix method. This model shows that the mode localization phenomenon exists on disordered stiffened beams both under free-free and hinged-hinged end conditions. The sensitivity of the response to attachment disorder (perturbations in rib stiffness and location) has also been examined. An elaborate vibrational and acoustic experiment has been carried out on a baffled, stiffened, two-span, hinged beam to examine the existence of the localized modes and verify the predicted acoustic responses. Moreover, the radiation efficiency of finite beams has been investigated for comparison of the radiation behavior presented by the different stiffened beam arrangements. A thorough investigation of mode localization, frequency passbands and stopbands, structural and acoustic intensities, and radiated acoustic power is presented for analysis of submerged infinite ribbed plates with variable rib materials geometry and spacing (periodic and nonperiodic). A second investigation of localized natural modes is demonstrated for analysis and experiment of finite stiffened beams in air. Dissert. Abstr.

A SEPARATION TECHNIQUE FOR ASYMPTOTIC-NUMERIC SOLUTION FOR GENERAL SHELLS OF REVOLUTION Ph.D. Thesis
Khaliq ur-Rehman Shad 1993 135 p
Avail: Univ. Microfilms Order No. DA9326558

Response of axisymmetric shell structures can be expressed through the state vector formulation for each circumferential harmonic of deformation. Based on the state vector equation and asymptotic method, an efficient approach for the solution of shells of revolution is presented in this study. At a transition point, where an asymptotic solution does not remain accurate, a new subelement is introduced by dividing the shell element into three parts. Through the introduction of subelement and division of the solution into the slowly varying and the rapidly varying solutions, the transition point problem is so handled, that the number of each type of solution remains constant in a subelement. The asymptotic solution is used for the rapidly varying solutions and power series for the slowly varying solutions over a reduced system of equations. The order of reduced system is the same as the total number of slowly varying solutions present. The method is applied to isotropic and anisotropic shells, and static as well as dynamic loading effects are handled. The technique developed enjoys the advantage of capturing the rapid variation in the behavior of shells over a coarse mesh, whereas purely numerical methods require a very fine mesh and a fair amount of user judgement to capture such a variation in the response of the shell structures. This rapid variation of solutions which is restricted to the edge effects for the problems of statics is present throughout the shell meridian in case of the dynamic response and stability problems, and it further enhances the importance of the present approach. As the solution in most parts is based on an analytic approach, time is saved in both setting up data and solving the problem. The accuracy and effectiveness of the approach is demonstrated in the several examples presented. These include shells of various geometry under different boundary conditions, the working out of resonant frequency and mode shapes for various types of shells, the effect of the degree of orthotropy and the variation of stress through the thickness of the composite shells. Dissert. Abstr.

VIBRATION LOCALIZATION IN DUAL-SPAN AXIALLY MOVING ELASTIC SYSTEMS Ph.D. Thesis
Abdulghaffar Azhari Aljawi 1993 188 p
Avail: Univ. Microfilms Order No. DA9319475

To date, vibration localization in the large class of systems modeled

by multispan axially moving materials has not been examined. These systems are common in many engineering applications, such as band saw blades, power transmission, belts and chains, and magnetic and paper tapes. An investigation of the vibration localization phenomenon in two-span, axially moving beams is presented. The effects of tension disorder, interspan coupling, and transport speed on the confinement of the natural modes of free vibration are studied. The equations governing the transverse vibration of the two-span, axially moving beam are derived through Hamilton's principle and solution methods are developed. Numerical results demonstrate that normal mode localization indeed occurs for both stationary and translating disordered two-span beams, especially for small interspan coupling. The occurrence of localization is characterized by a peak deflection much greater in one span than in the other. In the stationary disordered case, localization becomes more pronounced as interspan coupling decreases, i.e., as the span axial tension increases. For an axially translating beam with identical spans, the two loci in each pair of natural frequencies may exhibit a single or double crossing (depending on the value of tension) when plotted against the axial transport speed. These crossings become veerings when the beam is disordered, and localization is strongest at those speeds where the eigenvalue veerings occur. A perturbation approach, which provides additional insights into the sensitivity of the system to disorder, is also utilized. Analytical expressions are obtained in the limiting cases of weak and strong interspan coupling. Findings show that the sensitivity of the system to disorder primarily depends upon disorder and interspan coupling strengths. Finally, an investigation of the localization phenomenon is performed for a more complete model of a band/wheel system. The effects of tension disorder on the confinement of the natural modes of free vibration are investigated both theoretically and experimentally. It is shown that results obtained with the simple interspan coupling model are in qualitative agreement with those of the more complex model, thereby confirming the usefulness of the model featuring a simple coupling mechanism. Analytical predictions from the simple model are also very nicely validated by the experimental results. Dissert. Abstr.

INFLUENCES OF PRESSURE-SENSITIVE YIELDING AND NON-SINGULAR STRESS ON PLANE-STRESS ELASTIC-PLASTIC CRACK-TIP FIELDS Ph.D. Thesis
Zine El Abidine BenAoun 1993 103 p
Avail: Univ. Microfilms Order No. DA9319489

In this study, we investigate the effects of elasticity and nonsingular stress terms on the asymptotic plane-stress mode 1 crack-tip fields for pressure-sensitive materials under small scale yielding. Perfectly plastic behavior is assumed and plastic dilatancy is introduced by the normality flow rule. A closed-form general asymptotic solution for singular centered fan sectors is given as a function of mu which is a pressure sensitivity parameter introduced in the yield condition. When elastic perfectly plastic behavior is considered, the results of finite element computations show the existence of elastic sectors bordering the stress-free crack faces. The near-tip stresses of the finite element results agree well with those of the corresponding asymptotic analysis. The angular spans of the elastic and plastic sectors vary with the value of mu. They also vary, for a specific pressure sensitivity parameter, with the value of the nonsingular stress term (T-stress) in the asymptotic expansion of the linear elastic crack-tip stresses, which is the normal stress in the direction of the crack line. In particular, the elastic sector span is in general shown to decrease with increasing T-stress. The parameter mu as well as the nonsingular stress term also have significant effects on the sizes and shapes of the plastic zones. The contribution of hydrostatic stress in the yield criterion for this class of pressure-sensitive materials extends the boundary of the plastic zone much farther in front of the crack-tip than that for incompressible Mises materials. Also, as the T-stress increases, the height of the plastic zone increases substantially for materials with a large pressure sensitivity. In zirconia ceramics, the dilatational phase transformation strain from tetragonal to monoclinic phase is limited to 4 percent. This condition is also considered in our study. Our computational results show that the phase transformation zones for strong transformation zirconia ceramics with large mu can be approximated by those for elastic perfectly plastic materials with no limit on plastic dilatation strain. The phase transformation zone height and the corresponding radial variation of the phase transformation strain can be used to estimate the effects of the T-stress on toughening. Dissert. Abstr.

NONLINEAR EFFECTS IN INTERFACIAL FRACTURE Ph.D. Thesis
Philippe Hubert Geubelle 1993 245 p
Avail: Univ. Microfilms Order No. DA9316842

The issue of the non-coplanar quasistatic propagation of a crack in homogeneous and bimaterial sheets is investigated. Through a preliminary linear analysis, it is shown that the interface crack kinking problem is confronted, in most practical cases, with difficulties which do not arise in the homogeneous situation: the crack path as predicted by the maximum energy release rate criterion cannot be determined uniquely and an additional length parameter, absent in the homogeneous case, needs to be specified to assure uniqueness. Following that development, the assumption of small deformations is relinquished and it is shown how the size of the nonlinear zone imparts possibly the physical significance of the additional length parameter. The analysis is performed numerically in the homogeneous and bimaterial cases within the framework of the nonlinearly elastic theory of plane stress and using a 'boundary layer' approach. Material and geometrical nonlinearities are combined through the use of the Generalized Neo-Hookean (GNH) model. As the length of the crack extension becomes comparable to the size of the nonlinear zone, a transition is observed between the value of the energetically most favorable kink angle predicted by the linear theory and a unique a 'nonlinear' value which is found to be independent of the crack extension length and the far-field loading conditions. The results of the crack propagation analysis are related to those of a detailed asymptotic analysis of the structure of the near-tip stress and deformation fields for the GNH class of hyperelastic materials. The investigation addresses the symmetric (mode 1) and nonsymmetric (mixed-mode) homogeneous situations, the rigid substrate case, and the general bimaterial problem which allows for an arbitrary choice, on both sides of the interface, of the three material parameters characterizing the GNH model. The asymptotic analysis allows quantification of the effect of the 'hardening' characteristics on the blunting of the crack and the associated stress and strain singularities, and shows that the near-tip fields corresponding to a general nonsymmetric loading are, in the homogeneous situation, related to those of the symmetric (mode 1) case through a rotation which depends on the material characteristics and the far-field loading conditions. A somewhat similar property is obtained in the bimaterial problem, where the existence of a nonoscillatory and 'contact-free' solution is confirmed for all material combinations. Dissert. Abstr.

NONLINEAR VIBRATION ANALYSIS OF LAMINATED PLATES ON LINEAR AND NONLINEAR ELASTIC FOUNDATIONS Ph.D. Thesis
Yan-Shin Shih 1992 188 p
Avail: Univ. Microfilms Order No. DA9316784

Solutions to free undamped large amplitude vibrations of arbitrarily laminated thin rectangular and quadrilateral plates on elastic foundations based on an assumed mode shape are determined. S-S-S-S and C-C-C-C boundary conditions with movable and immovable edges are considered in chapter 3. S-S-S-S, C-S-C-S, and C-C-C-C boundary conditions with stress-free edges of rectangular and quadrilateral plates are considered in chapters 4 and 5. The governing equations of motion of plates on linear Winkler, Pasternak foundations and a nonlinear Winkler foundation are provided using von Karman's theory. The Galerkin's method reduces the von Karman equation to a time-dependent ordinary differential equation and solutions are then obtained by using the Runge-Kutta method. The effects on the nonlinear frequency of several parameters such as amplitude, material lamination, aspect ratio, and boundary conditions as related to stress-free edges and the influence of elastic foundation constants are provided. Dissert. Abstr.

EXPERIMENTAL MEASUREMENT OF DYNAMIC FAILURE AND FRAGMENTATION PROPERTIES OF METALS
D. E. Grady and M. E. Kipp 1993 30 p Presented at the National Science Foundation (NSF) Symposium on Dynamic Failure Mechanics of Modern Materials, Pasadena, CA, 3-5 Feb. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC04-94AL-85000)
(DE94-007377; SAND-93-2679C; CONF-940256-1) Avail: Issuing Activity (Department of Energy (DOE))

An experimental method for determining failure and fragmentation properties of metals in catastrophic breakup events has been pursued in this work. Spherical samples of the test metals were launched at high velocities with a two-stage light-gas gun facility and subjected to controlled impulsive loading by impact on a stationary non-metallic plate. Fragmentation and motion of the debris were diagnosed with multiple flash radiography. Methods for determining critical failure properties and the fragmentation toughness of the test metals were explored. DOE

ELASTIC AS LIMIT OF VISCOELASTIC RESPONSE, IN A CONTEXT OF SELF-SIMILAR VISCOUS LIMITS Summary Report
Anthanasios E. Tzavaras Mar. 1994 38 p
(Contract N00014-93-C-0015; NSF DMS-92-09049)
(AD-A277043) Avail: CASI HC A03/MF A01

We study the equations of one-dimensional isothermal elastic response as the small viscosity limit of the equations of viscoelasticity, in a context of self-similar viscous limits for Riemann data. THe limiting procedure is justified and a solution of the Riemann problem for the equations of elasticity is obtained. The emerging solution is composed of two wave fans, each consisting of rarefactions, shocks and contact discontinuities, separated by constant states. At shocks the self-similar viscous solution has the internal structure of traveling waves, and an admissibility criterion identified by Wendroff is fulfilled. DTIC

CONTROL AND STABILIZATION OF DISTRIBUTED PARAMETER SYSTEMS; THEORETICAL AND COMPUTATIONAL ASPECTS Final Report
I. Lasiecka and R. Triggiani Feb. 1994 98 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0511-89)
(AD-A277239; UVA/525714/AM94/101; AFOSR-94-0054TR) Avail: CASI HC A05

In this research, the issue of uniform stabilization has been investigated for large classes of conservative systems arising in elasticity. In the case of linear problems, two types of feedback have been considered: dissipative feedback operators acting only on the 'velocity' and generally nondissipative feedback based on Riccati operators and acting on the full pair of position and velocity. In nonlinear problems, feedback of the first type have been studied. Numerical implementation for both types of feedbacks have received special attention. DTIC

DYNAMIC ERROR COMPENSATION IN ROBOTIC TRUSSES Ph.D. Thesis
Allen R. Boronkay 1993 385 p
Avail: Univ. Microfilms Order No. DA9326429

A robotic truss is an active structure comprised of links which inherently can be loaded only in tension or compression. Unlike passive truss structures, a robotic truss can execute large motions by adjusting the lengths of its links through the use of actuators. The importance of the truss structure for robotics has been neither fully recognized nor fully exploited in prior work. This property and its consequences for design are the focus of this thesis. Robotic trusses are shown to have advantages in metrology, modularity, stiffness-to-weight ratio, natural frequencies, modeling, and simplicity. The robotic truss's qualities make dual coarse/fine actuation interesting for some applications, such as machining. In dual actuation, each leg of the robotic truss has two actuators, one for large, relatively slow motions and one for small, high speed motions. A dynamic model for a simple robotic truss with dual actuation and control strategies for it, including the possibility for distributed control, are developed. The model is used to show that a dual actuated robotic truss can achieve a dynamic stiffness of over 200 N/micron (1.14 x 10(exp 6) lb/in.) which is sufficient for precision machining. The modeling, design, construction, and performance of an experimental differential solenoid fine actuator are examined. While this work uses machining as a focus, the robotic truss may find innumerable other applications. It is especially appropriate for cases in which high precision is needed. Electronics assembly, in particular, could benefit from the robotic truss's combination of metrological advantages and high natural frequencies. Dissert. Abstr.

AUTOMATIC CONTACT IN DYNA3D FOR VEHICLE CRASHWORTHINESS
R. G. Whirley and B. E. Engelmann 15 Jul. 1993 17 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-007143; UCRL-JC-114598; CONF-931121-38) Avail: CASI HC A03

This paper presents a new formulation for the automatic definition and treatment of mechanical contact in explicit nonlinear finite element analysis. Automatic contact offers the benefits of significantly reduced model construction time and fewer opportunities for user error, but faces significant challenges in reliability and computational costs. This paper discusses in detail a new four-step automatic contact algorithm. Key aspects of the proposed method include automatic identification of adjacent and opposite surfaces in the global search phase, and the use of a smoothly varying surface normal which allows a consistent treatment of shell intersection and corner contact conditions without ad-hoc rules. The paper concludes with three examples which illustrate the performance of the newly proposed algorithm in the public DYNA3D code. DOE

(DE94-007184; WSRC-MS-94-080; CONF-931234-8) Avail: CASI HC A02

This study provides numerical procedures to model 40-cm-diameter, schedule 40, Type 304L stainless steel pipe girth welding and a newly proposed post-weld treatment. The treatment can be used to accomplish the goal of imparting compressive residual stresses at the inner surface of a pipe girth weldment to prevent/retard the intergranular stress corrosion cracking (IGSCC) of the piping system in nuclear reactors. This new post-weld treatment for mitigating residual stresses is cooling stress improvement (CSI). The concept of CSI is to establish and maintain a certain temperature gradient across the pipe wall thickness to change the final stress state. Thus, this process involves sub-zero low temperature cooling of the inner pipe surface of a completed girth weldment, while simultaneously keeping the outer pipe surface at a slightly elevated temperature with the help of a certain heating method. Analyses to obtain quantitative results on pipe girth welding and CSI by using a thermo-elastic-plastic finite element model are described in this paper. Results demonstrate the potential effectiveness

of CSI for introducing compressive residual stresses to prevent/retard IGSCC. Because of the symmetric nature of CSI, it shows great potential for industrial application. DOE

VIBRATION DAMPENER AND METHOD FOR MAKING SAME Patent Application
Wendell Maciejewski, inventor (to Navy) 22 Nov. 1993 14 p
(AD-D016094; US-Patent-Appl-SN-155606) Avail: CASI HC A03/MF A01

There is disclosed a vibration dampener comprising a body for disposition between two relatively movable members, the body being formed from a carrier of a gel material and particles having electrorheological properties embedded in the carrier with the particles electrically aligned and pseudo-bonded. Upon a displacement force being applied to the body, as by one of the members, the particles resist motion relative to other of the particles. There is further disclosed a method for making the aforesaid vibration dampener wherein the dampener has a current passed through it while the carrier cures into a gel material. DTIC

Avail: CASI HC A03/MF A01

Through the use of equivalent variable analogies, the authors demonstrate how an electrical subsystem can be modeled by an equivalent structural subsystem. This allows the electrical subsystem to be probabilistically analyzed by using available structural reliability computer codes such as NESSUS. With the ability to analyze the electrical subsystem probabilistically, we can evaluate the reliability of systems that include both structural and electrical subsystems. Common examples of such systems are a structural subsystem integrated with a health-monitoring subsystem, and smart structures. Since these systems have electrical subsystems that directly affect the operation of the overall system, probabilistically analyzing them could lead to improved reliability and reduced costs. The direct effect of the electrical subsystem on the structural subsystem is of secondary order and is not considered in the scope of this work. Author

REACTOR PRESSURE VESSEL STRUCTURAL INTEGRITY RESEARCH IN THE US NUCLEAR REGULATORY COMMISSION HSST AND HSSI PROGRAMS
W. E. Pennell and W. R. Corwin 1994 10 p Presented at the British Nuclear Energy Society International Conference on Thermal Reactor Safety Assessment, Manchester, England, 23-26 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-006550; CONF-940594-1) Avail: CASI HC A02

This report discusses development on the technology used to assess the safety of irradiation-embrittled nuclear reactor pressure vessels containing flaws. Fracture mechanics tests on reactor pressure vessel steel have shown that local brittle zones do not significantly degrade the material fracture toughness, constraint relaxation at the crack tip of shallow surface flaws results in increased fracture toughness, and biaxial loading reduces but does not eliminate the shallow-flaw fracture toughness elevation. Experimental irradiation investigations have shown that the irradiation-induced shift in Charpy V-notch versus temperature behavior may not be adequate to conservatively assess fracture toughness shifts due to embrittlement and the wide global variations of initial chemistry and fracture properties of a nominally uniform material within a pressure vessel may confound accurate integrity assessments that require baseline properties. OVERVIEW OF SHOCK PHYSICS CODES FOR ARMOR ANALYSIS
M. McGlaun 1993 8 p Presented at the 5th Annual TACOM Combat Vehicle Survivability Symposium, Monterey, CA, 28 Feb. - 3 Mar 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-94AL-85000)
(DE94-008948; SAND-93-2552C; CONF-940255-1) Avail: Issuing Activity (Department of Energy (DOE))

Shock physics codes for armor analysis and the computers used to run the codes have improved dramatically over the last five years. Improved algorithms and material models allow accurate and efficient modeling of conventional armor. Desktop workstations routinely perform two-dimensional calculations, and massively parallel computers can perform three-dimensional calculations. New developments in codes and computers promise improved accuracy, increased capabilities, and faster simulation. This paper describes the current state of armor analysis codes and the computers used to run the codes. Armor analysis code features fall into one of five categories: mesh, solution algorithm, material model, heuristic, or computer. This paper discusses the current state of each of these categories and discusses the additional work needed. DOE

The aeroelastic stability of a two-dimensional cascade oscillating in supersonic axial flow is analyzed in the time domain. The aeroelastic model consists of a single degree of freedom typical section structural model for each blade of the cascade and an unsteady two-dimensional cascade aerodynamic model based on the Euler equations. The Euler equations are solved using a time accurate Alternating Direction Implicit (ADI) solution scheme. The aeroelastic equations are integrated in time. The effect of interblade phase angle is included in the aeroelastic analysis by an appropriate choice of initial and boundary conditions. Flutter predictions are obtained from the time response of a flat plate cascade in single degree of freedom pitching motion. The results correlate well with those obtained from a separate frequency domain flutter analysis for all values of interblade phase angles considered. Flutter results are then presented for cascades having airfoil sections representative of a supersonic throughflow fan. The validity of the time integration method for a cascade of airfoils at various interblade phase angles is demonstrated. Author

LIMITING VIBRATION IN SYSTEMS WITH CONSTANT AMPLITUDE ACTUATORS THROUGH COMMAND PRESHAPING M.S Thesis - MIT
Keith Eric Rogers May 1994 117 p
(Contract NAS9-18426)
(NASA-CR-188284; NAS 1.26:188284; CSDL-T-1214) Copyright Avail: CASI HC A06/MF A02

The basic concepts of command preshaping were taken and adapted to the framework of systems with constant amplitude (on-off) actuators. In this context, pulse sequences were developed which help to attenuate vibration in flexible systems with high robustness to errors in frequency identification. Sequences containing impulses of different magnitudes were approximated by sequences containing pulses of different durations. The effects of variation in pulse width on this approximation were examined. Sequences capable of minimizing loads induced in flexible systems during

execution of commands were also investigated. The usefulness of these techniques in real-world situations was verified by application to a high fidelity simulation of the space shuttle. Results showed that constant amplitude preshaping techniques offer a substantial improvement in vibration reduction over both the standard and upgraded shuttle control methods and may be mission enabling for use of the shuttle with extremely massive payloads. COMPLIANCE MEASUREMENTS OF CHEVRON NOTCHED FOUR POINT BEND SPECIMEN

Anthony Calomino, Raymond Bubsey, and Louis J. Ghosn Apr. 1994 26 p

(RTOP 505-63-12)

(NASA-TM-106538; E-8679; NAS 1.15:106538) Avail: CASI HC A03/MF A01

The experimental stress intensity factors for various chevron notched four point bend specimens are presented. The experimental compliance is verified using the analytical solution for a straight through crack four point bend specimen and the boundary integral equation method for one chevron geometry. Excellent agreement is obtained between the experimental and analytical results. In this report, stress intensity factors, loading displacements and crack mouth opening displacements are reported for different crack lengths and different chevron geometries, under four point bend loading condition. STRAIN SENSING USING OPTICAL FIBERS Final Report

Richard Houghton and Steven Hiles 6 May 1994 192 p

(Contract NCC8-8)

(NASA-CR-195807; NAS 1.26:195807; TR-MCTR-0594-07; TTU-124-894-83) Avail: CASI HC A09/MF A02

The main source of attenuation which will be studied is the optical fiber's sensitivity to bending at radii that are much larger than the radius of the fiber. This type of environmental attenuation causes losses that are a function of the severity of the bend. The average attenuation caused by bending varies exponentially with the bend radius. There are many different fibers, sources, and testing equipment available. This thesis describes tests that were performed to evaluate the variables that effect bending related attenuation and will discuss the consistency of the results. Descriptions and comparisons will be made between single mode and multimode fibers as well as instrumentation comparisons between detection equipment. Detailed analysis of the effects of the whispering gallery mode will be performed along with theorized methods for characterization of these modes. Derived from text

AN ANALYTICAL STUDY OF THE VIBRATION OF BEAMS FITTED WITH NEUTRALIZERS. PART 2: ASSESSMENT OF THE EFFECTS OF MOUNTING CONFIGURATIONS

P. Clark and R. G. White Jan. 1993 66 p

(ISVR-TR-225-Pt-2) Copyright Avail: Issuing Activity (Inst. of Sound and Vibration Research, Univ. of Southampton, Southampton SO9 5NH, England)

The control of vibration in beams or other one-dimensional structures is of considerable interest in practical engineering. With the majority of industrial machinery installations it is this type of structure, for example, pipe work and other mechanical linkages, which forms one of the main vibration paths which bypass isolator systems. It is well-known that the introduction of discontinuities into these types of structures significantly affects the vibration transmission properties of the complete system. One such discontinuity is the vibration neutralizer. In this report, the effects of mounting configuration upon the performance of the device as a vibration attenuator are presented using the concept of vibrational power transmission. Author

EFFECTIVE COMPUTATIONAL STRATEGY FOR PREDICTING THE RESPONSE OF COMPLEX SYSTEMS Final Report, 30 Sep. 1990 - 31 Aug. 1993

Ahmed K. Noor 8 Dec. 1993 25 p

(Grant AF-AFOSR-0369-90)

(AD-A277452; UVA/525733/CEAM94/101; AFOSR-94-0096TR) Avail: CASI HC A03/MF A01

An effective computational strategy is developed for generating the response of complex systems using (small or large) perturbations from the response of a simple structure (or a simpler mathematical/discrete model of the original structure). Two general approaches are developed for selecting the simpler model and establishing the relations between the original and simpler models. The two approaches are: decomposition or partitioning strategy, and hierarchical modeling strategy. Two effective partitioning strategies are used. The first is based on uncoupling of load-carrying mechanisms, and the second is based on symmetry transformations. The hierarchical modeling used is a predictor-corrector iterational process based on using a simple mathematical model in the predictor phase and correcting the response using a more accurate mathematical model. The strategies have been applied to several problems including: thermal buckling and postbuckling of multilayered composite plates; and nonlinear dynamic analysis of composite shells. DTIC

STRUCTURAL DAMPING STUDIES AT CRYOGENIC TEMPERATURES

Clarence P. Young, Jr. (North Carolina Univ., Raleigh.) and Ralph D. Buehrle May 1994 34 p

(RTOP 505-59-54-01)

(NASA-TM-109073; NAS 1.15:109073) Avail: CASI HC A03/MF A01

Results of an engineering study to measure changes in structural damping properties of two cryogenic wind tunnel model systems and two metallic test specimens at cryogenic temperatures are presented. Data are presented which indicate overall, a trend toward reduced structural damping at cryogenic temperatures (-250 degrees F) when compared with room temperature damping properties. The study was focused on structures and materials used for model systems tested in the National Transonic Facility (NTF). The study suggests that the significant reductions in damping at extremely cold temperatures are most likely associated with changes in mechanical joint compliance damping rather than changes in material (solid) damping. NONLOCAL THEORY FOR FRACTURING OF QUASIBRITTLE MATERIALS Final Report

Zdenek P. Bazant 1 Mar. 1994 220 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant AF-AFOSR-0140-91)

(AD-A278283; Rept-0650-350-0457; AFOSR-94-0204TR) Avail: CASI HC A10

The failure of quasibrittle materials, which include concrete, rock, high-performance ceramics and fiber composites, cannot be treated according to the classical theories of plasticity or fracture mechanics because growth of zones of strain softening damage due to cracking must be considered. The mathematical treatment involves difficulties with spurious excessive localization. To remedy them, the nonlocal continuum concept was previously introduced, however, without theoretical foundation. The principal objective of the research has been to formulate the nonlocal damage concept on the basis of micromechanics of systems of growing and interacting cracks. This has led to a new model in which the nonlocal interactions are based on a smeared crack influence function, are tensorial and directional, and directional, and exhibit a power-type long-range decay. An iterative method for solving a Fredholm integral equation for the crack interactions in a finite element code has also been formulated. Advances have further been made in several related problems of micro-macro correlation. The applicability limits of the classical Weibull theory of random micro-strength have been identified and a nonlocal probabilistic generalization derived. The time dependence and rate effect in damage evolution have been described on the basis of the activation theory for bond ruptures. The problems of scaling and size effect associated with damage have

been analyzed, both theoretically and experimentally (with tests on concretes, fiber composites and rocks). DTIC

FUNDAMENTAL STUDIES IN CRACK INITIATION Annual Report, 15 Sep. 1992 - 14 Sep. 1993
John Botsis Oct. 1993 38 p
(Contract F49620-92-J-0493)
(AD-A278387; AFOSR-94-0227TR) Avail: CASI HC A03/MF A01

Mechanistic investigations of damage evolution before crack initiation in an amorphous polymer show that damage consists of a core of highly dense crazing and a peripheral less dense zone of crazing. Damage characterization is carried out at consecutive configurations of the damage zone. Analysis of the kinematics of damage at different times involves comparisons of the inertia moments of damage distributions. The results indicate that damage evolution between consecutive configurations can be approximated by a linear transformaiion of the space variables. Thus, the process of damage growth can be described by translation and deformation of the damage zone. The growth rates of the damage zone movements decrease until crack initiation. In all cases, the average densities exhibit a damping type behavior with the number of cycles. The crack initiates within a core zone immediately ahead of the stress concentrator. The experimental results suggest that damage density within the core zone is independent of the loading conditions considered herein. This value is approximately equal to the damage density around the crack tip during slow crack propagation. The crack length at initiation is found to increase exponentially with the stress level. A simple decaying exponential relationship relates the crack initiation times and the applied stress level. This result is consistent with the fracture models based on absolute reaction theories. The Joint US-Japan Seminar in the Environmental Sciences was based on the premises that questions remain concerning the factors that control many of the regularities observed in ecological communities and that increased collaboration between researchers in the United States and Japan can contribute to answering these questions. The papers included in this report resulted from the Seminar. These papers as well as workshop discussions summarized here outline the main issues that face theoretical ecology today. The papers cover four different areas of theoretical ecology: (1) individual species adaptations, (2) ecological community-food web interactions, (3) food web theory, and (4) concepts related to the ecosystem. Individual projects are processed separately for the databases. DOE

The United States is spending oillions of dollars in a multiyear Global Change Research Program (the USGCRP) to monitor, understand, and ultimately predict the nature of global changes and the mechanisms that cause them. The background report examines the direction and scope of USGCRP and its most expensive component, NASA's Earth Observing System (EOS) of satellites. In particular, it examines how well USGCRP and EOS are fulfilling their scientific objectives, whether some program elements are missing or need to be strengthened, and whether the program is meeting the needs of policymakers. The background paper describes the number of suggestions to improve the value of the USGCRP to both scientists and policymakers. The background paper also explicates the continuing debate over whether the sensors and satellites planned by USGCRP: (1) will be able to acquire data in sufficient detail to elucidate the mechanisms responsible for global change; and (2) are appropriate for long-term monitoring of key indices of global change. FILTERING OF SATELLITE ALTIMETRY DATA WITH OPTIMAL SMOOTHING CUBIC SPLINES TO COMPUTE GEOID HEIGHTS, ALONG-TRACT GEOID AND GRAVITY GRADIENTS IN THE INDONESIAN WATERS AND ITS SURROUNDINGS
R. Rummel Sep. 1993 143 p See also PB87-213336 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-147527) Avail: CASI HC A07

In the report, at first the basic principles of satellite altimetry and its oceanographic, geophysic and geodetic applications are discussed. Since the authors use the Geosat/ERM data, a review of the Geosat Satellite is briefly given. The theory behind the method to compute the geoid gradients and gravity gradients is described. The method takes advantage of the high precision and the data density in profile direction. For obtaining the vertical components a transformation from an oblique system into an orthogonal system is needed. Problems in the construction of geoid heights as a function of obtained distance, and the filtering of noise will be solved with optimal smoothing cubic splines using the GCV-criterion yielding the minimal value of the true mean square error. Next to the function, the error of the spline function will be estimated using the propagation law of covariances. NTIS

APPLICATION OF RADON TRANSFORMATION FOR IMPROVED ANALYSIS OF SPARSELY SAMPLED DATA: A FEASIBILITY STUDY
R. F. Hanssen Nov. 1993 151 p See also PB93-197283 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-147535) Avail: CASI HC A08

The Radon transform depicts line-integrals in the space domain as pointvalues in the Radon domain. The set of all possible line-integrals yields a continuous coverage of the Radon domain. In this manner, lineations in the space domain become visible in the Radon domain, as they have a deviating Radon amplitude. The location of this amplitude represents the position parameters of the corresponding line. The Radon domain representation can also be found for a discrete homogeneously sampled set of data. The first impulse for this study originates from the field of satellite altimetry, and therefore the authors will throughout this thesis now and then refer to altimetry and altimetry data. Satellite altimetry has become an important technique for studying several properties of ocean areas, as

well for geodesists as for oceanographers, climatologists, geophysicist etc. A satellite altimeter measures the shape of the ocean surface which is simultaneously a good approximation of the marine geoid (i.e. the equipotential ocean surface). For geodetic or geophysical applications, it is desirable to compute the gravity anomaly or vertical deflection from the geoid height. NTIS

(TELECOM-93-E-001; ETN-94-95895) Avail: CASI HC A09

An attempt to formalize aspects related to multisensor fusion is made. The characterization of the fact that a sensor may be redundant, or complementary in relation to another sensor, is addressed. For this, information theory provides a very important mathematical framework, allowing quantitative measurement of the redundancy or complementary levels existing between two sensors. A formalization of concepts encountered in multisensor fusion allowing better development of potential fusion strategies is proposed. A generic cell of data fusion is defined, attempting to characterize whichever data fusion process. The problem of integration can then, in this formalization, be regarded as the association of different fusion cells. Within the framework of this formalization, two types of strategies aiming at detecting bridges, and extracting build-up areas, are examined. An expert system for interpretation allowing simultaneous detection of several types of objects to be controlled is presented. This system is based on a modeling of manipulated objects (sensors, semantic objects, image primitives, etc.) satisfying description independence constraints. It lies on a blackboard type architecture, which seems particularly well suited to the management of several sensor usage. The study results show the indispensable character of multisensor fusion in scene analysis. ESA

(Contract DAAL03-89-G-0108)
(AD-A276022; ARO-27259.2-GS-SAH) Avail: CASI HC A07/MF A02

Based on a unique experimental technique, measurement results are presented on the passive, remote sensing of the optical modulation transfer function of desert atmospheres (MTF(sub A)), including the DC, low, and high spatial cutoff frequency components which are attributed to contrast, aerosol, and turbulence, respectively. In particular, use of this technique has made it possible to directly measure the low spatial frequency cutoff of the aerosol component. This technique is based on utilizing digital image processing of remote video scenes which include two optically identical castellated targets which are located at different distances and are contrasted against the horizon sky. Ratios of apparent contrast and FFT calculations are used to determine the MTF(sub A) components, including the spatial cutoff frequencies of the aerosol and turbulence components, independent of the imaging system and actual properties of the targets. The experimental technique is described along with current MTF(sub A) component measurements. DTIC

GAS HYDRATE DETECTION AND MAPPING ON THE US EAST COAST
T. S. Ahlbrandt and W. P. Dillon 1993 20 p Presented at the Fuels Technology Contractors' Review Meeting, Morgantown, WV, 16-18 Nov. 1993
(Contract DE-AI21-83MC-20422)
(DE94-005959; DOE/MC-20422/94/C0315; CONF-931156-15) Avail: CASI HC A03/MF A01

Project objectives are to identify and map gas hydrate accumulations on the U.S. eastern continental margin using remote sensing (seismic profiling) techniques and to relate these concentrations to the geological factors that control them. In order to test the remote sensing methods, gas hydrate-cemented sediments will be tested in the laboratory and an effort will be made to perform similar physical tests on natural hydrate-cemented sediments from the study area. Gas hydrate potentially may represent a future major resource of energy. Furthermore, it may influence climate change because it forms a large reservoir for methane, which is a very effective greenhouse gas; its breakdown probably is a controlling factor for sea-floor landslides; and its presence has significant effect on the acoustic velocity of sea-floor sediments. DEVELOPMENT OF A STATISTICAL METHOD FOR ESTIMATING THE DOWNWARD LONGWAVE RADIATION AT THE SURFACE FROM SATELLITE OBSERVATIONS Ph.D. Thesis
Hai-Tien Lee 1993 166 p
Avail: Univ. Microfilms Order No. DA9327454

A new technique was developed statistically for estimating the DLR using the HIRS/2 clear-column radiances from NOAA polar orbiting satellites. Simulated radiation data were used in the model development and validation. Two categories of regression equations were studied. They are the linear models and the emissivity/transmissivity-approach models. It was found that the emissivity/transmissivity models are superior than the linear ones in the aspects of the RMS errors of the DLR estimates as well as in the residual spread patterns. For both clear and cloudy conditions, when instrument noise is included, the regression RMS errors of the emissivity and transmissivity models range from about 4 to 9 W/sq. m. Sensitivity studies show that DLR is the most sensitive to the error in the cloud amount on average. Overall, the combined DLR errors, excluding the contribution of the error in the surface pressure estimation, range from about 7 to 12 W/sq. m when there are +/- 10% uncertainties in cloud base heights. When the cloud amount uncertainties rise to 30%, the range of the combined DLR error ranges from about 10 to 25 W/sq. m. The standard deviations of DLR differences found in the validations are about 9 W/sq. m with mean differences at about +/-1 W/sq. m. For cloudy skies, cloud base height and the effective cloud amount are needed. The DLR estimated with different cloud data sources, however, has not been examined. Since the sensitivity study shows that the DLR error due to the uncertainty of the cloud amount usually dominates the other error components, it is believed that an accurate estimate of the cloud amount is more important for cloudy-sky DLR estimation. Despite these limitations noted above, our analysis indicates that the physical statistical method developed in this study should provide estimates of the DLR to within about 10 W/sq. m RMS directly from the HIRS observations if the cloud properties can be accurately estimated. Furthermore, it is expected that the errors will be considerably smaller for monthly average, except where persistent extreme conditions occur. Dissert. Abstr.

SATELLITE RADAR ALTIMETRY OVER THE CONTINENTAL ICE SHEETS Ph.D. Thesis
Curt H. Davis 1992 192 p
Avail: Univ. Microfilms Order No. DA9313095

We conducted a review of the dielectric and physical properties of ice and snow to determine estimates for the depth of penetration in dry polar snow at altimeter frequencies. Minimum penetration estimates between 6 to 9 m were calculated for dry polar snow based upon the most recent reported dielectric data. In addition, an analysis of in situ radar data from East Antarctica showed that the penetration depth of dry polar snow varied with surface elevation and distance from the coast. By approximating the altimeter's antenna pattern and transmitted pulse shape with Gaussian functions, we derived a closed-form analytical solution for the return power volume scattered from beneath the ice sheet surface. The volume scattering model was then combined with the Brown surface scattering model. By applying the combined model to averaged altimeter waveforms, we showed that it accurately described variations in altimeter waveform shapes produced by differing contributions of surface and volume scattering to the received power. Next we developed an algorithm based upon the combined surface/volume scattering model that is capable of retracking individual (10/s) altimeter waveforms. Because the model is nonlinear, an iterative least-squares procedure was used to fit the combined model to altimeter return waveforms. The algorithm was used to retrack over 400,000 return waveforms from the Greenland and Antarctic ice sheets. By retracking individual altimeter waveforms we made quantitative estimates of the

geographical and seasonal variations in the near-surface properties of the ice sheet. The surface properties were correlated with elevation, latitude, and microwave brightness temperature data. Specifically, the estimated extinction coefficient of snow, k(sub e), varied from 0.48 to 0.13 m(exp -1) over the latitudes from 65 to 72 deg N on the central portion of the Greenland ice sheet and from 0.20 to 0.10 m(exp -1) over a section of Wilkes land in East Antarctica where the elevation increased from 2550 to 3150 m. Also, significant seasonal variations in the surface properties were observed in some areas of both the Greenland and Antarctic data sets. Finally we compared the surface elevations estimated from our retracking algorithm with the surface elevations produced from the NASA and ESA retracking algorithms. The NASA algorithm produced the most accurate elevation-change estimates when seasonal variations were present. Dissert. Abstr.

POSSIBLE IMPROVEMENTS OF SATELLITE EPHEMERIS PROGRAMS USED IN GEODESY

R. J. Valten Aug. 1993 106 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-148681) Avail: CASI HC A06

Possible improvements of ephemeris programs with respect to process speed are discussed. For some special cases fast algorithms are examined. These algorithms are tested in the program IRVORB. Satellite orbit dynamics (SOD) is discussed in chapter 2 to illustrate the origin of the formulae which are used in chapters 4, 5, and 6. Chapter 3 discusses some general considerations that must be made when programming computers. The first algorithm, which might improve process speed, is discussed in chapter 4. It concerns the iteration of the elliptic Kepler equation. Chapter 5 discusses the geopotential acceleration. Koop and Stelpstra introduced a fast recursion scheme for the calculation of Legendre functions and their derivatives. This method is implemented in IRVORB for the calculation of the geopotential acceleration. A third attempt to improve the process speed of orbital routines is discussed in chapter 6. Chapter 7 discusses the main results of this study. NTIS

HYDROLOGIC DATABASE USER'S MANUAL

J. B. Champman, K. J. Gray, and C. B. Thompson Sep. 1993 102 p
(Contract DE-AC08-90NV-10845)
(DE94-003950; DOE/NV-10845/31) Avail: CASI HC A06/MF A02

The Hydrologic Database is an electronic filing cabinet containing water-related data for the Nevada Test Site (NTS). The purpose of the database is to enhance research on hydrologic issues at the NTS by providing efficient access to information gathered by a variety of scientists. Data are often generated for specific projects and are reported to DOE in the context of specific project goals. The originators of the database recognized that much of this information has a general value that transcends project-specific requirements. Allowing researchers access to information generated by a wide variety of projects can prevent needless duplication of data-gathering efforts and can augment new data collection and interpretation. In addition, collecting this information in the database ensures that the results are not lost at the end of discrete projects as long as the database is actively maintained. This document is a guide to using the database. DOE

Data collection by detecting electromagnetic radiation reflected or emitted from objects on the Earth surface (remote sensing) is addressed. When detecting terrestrial materials with remote sensing systems (sensors and platforms) from satellite, the atmosphere affects electromagnetic energy levels and limits usable wavelength bands. Short wavelengths of electromagnetic radiation (gamma, X and UV portions of electromagnetic spectrum) are reflected almost totally from water vapor, which is always present in the atmosphere. Also atmospheric gas molecules and particles such as aerosols, dust, haze, smoke, etc. cause absorption and scattering of radiation energy on their own special spectral regions. The drawback of absorption and scattering can often be avoided by using more suitable, less affected wavelength bands. For example water vapor affects very little on microwave radiation and so imaging using this band is possible through clouds. Microwave detection can also be used at night time as the system itself supplies the detected radiation. Radar sensors are examples of active remote sensing instruments. Each terrestrial feature has its own reflectance and emittance characteristics, which often identify the imaged feature and its state. By using remote sensing images it is often possible get information also at features on which solar radiation can not reach directly. For example terrestrial plants often tell about the properties of soil under them. ESA

ESTIMATION OF VISIBLE AND NEAR-INFRARED REFLECTIVITY FOR PEYTO GLACIER BASIN USING SATELLITE DATA M.S. Thesis

Andrew Timothy Lowe 1993 142 p
(ISBN-0-315-87039-7; CTN-94-61241) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Performance of energy balance models in simulating glacier mass balance depends on the accurate representation of the spatial variation of surface reflectivity. A method is presented for estimating surface reflectivity from Landsat-5 imagery and digital terrain data. A two-stream solar radiation model is constructed to compute the incoming shortwave irradiance, path radiance, and vertical transmission for a homogeneous atmosphere. Topographic correction is made using digital terrain data. Landsat-5 band reflectances corrected for atmospheric effects are combined into a measure of surface reflectivity for the visible, near-infrared, and total portions of the solar spectrum using a simple weighting strategy. The procedure is applied to Peyto Glacier Basin, Alberta. The two-stream solar radiation model performs well. Estimated surface reflectivity measurements indicate considerable agreement with the field observations and literature. The study also demonstrates the sensitivity of snow and ice reflectivity to variations in slope angle and orientation. Author (CISTI)

THE EUROPEAN IMAGING SPECTROSCOPY AIRBORNE CAMPAIGN (EISAC). DATA TAKES AND EVALUATION PROGRAMME: AN OVERVIEW

J. Bodechtel and S. Sommer *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 7-12 (For primary document see N94-31853 09-43)
Copyright Avail: CASI HC A02/MF A02

The activities of the European Imaging Spectroscopy Airborne Campaign (EISAC) initiated jointly by the European Space Agency (ESA) and the Joint Research Center (JRC) of the Commission of the European Communities, are summarized. In the framework of the campaign, flights

over 7 European test sites were performed in May/Jun. 1989. The EISAC data evaluation program comprised a wide range of applications in agriculture, forestry, geology/pedology and oceanography/marine biology. In a first phase, data evaluation was concentrated on quality assessment, radiometric and atmospheric correction of the airborne data. The second phase dealt with spectra signature modeling and with the definition and evaluation of relevant surface parameters, aiming towards optimized approaches for the exploitation of the data of future spaceborne imaging spectrometers with medium and high spatial resolution. NORSMAP 1989: NORWEGIAN REMOTE SENSING SPECTROSCOPY FOR MAPPING AND MONITORING OR ALGAL BLOOMS AND POLLUTION

Lasse H. Pettersson, Ola M. Johannessen, and Oeyvind Frette *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 17-25 Sponsored by Norwegian State Pollution Control Authority; Royal Norwegian Council for Scientific and Industrial Research; and Norwegian Space Center (For primary document see N94-31853 09-43)

Copyright Avail: CASI HC A02/MF A02

NORSMAP, a multi-institutional research program established to evaluate the potential of airborne imaging spectrometry for the monitoring of algal blooms in the North and Adriatic Seas, is reported. A Compact Airborne Spectrographic Imager (CASI) was operated from surveillance aircraft for a three week period in May 1989. The European Imaging Spectrometry Airborne Campaign (EISAC'89) also selected the NORSMAP region as one of the test sites to be flown over by the Fluorescence Line Imager (FLI) and the 64 channel Geophysical Environmental Research (GER) corporation Imaging Spectrometer (GERIS). The airborne activities were coordinated with field investigations carried out by research vessels. These measurements covered a wide range of physical, biological and optical ocean parameters. A spectrometer was installed on the research vessels to provide near surface waterleaving radiance spectra. In addition, a large number of other in situ biological, optical, and physical parameters were measured. Water masses covering a wide range of optical properties were analyzed and chlorophyll a concentrations in the range from 0.8 to 5 microg/l were observed. A good large scale match between the in situ and airborne data are found, although the point to point comparison are not too convincing. ESA

ANALYSIS OF GER IMAGING SPECTROMETRY DATA FOR THE IDENTIFICATION OF SOIL AND VEGETATION PARAMETERS IN LAND DEGRADATION STUDIES

Joachim Hill, Wolfgang Mehl, and Jacques Megier *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 27-33 (For primary document see N94-31853 09-43)

Copyright Avail: CASI HC A02/MF A02

The potential use of remote sensing techniques, especially using the Geophysical Environment Research (GER) corporation imaging spectrometer, for ecological surveys in the Mediterranean area, at local and regional scales, are assessed. The aim was to identify and monitor degradational processes that may result from the instability of the biological communities, the accelerated erosion by water, and accidental or deliberate fires. In order to efficiently use remotely sensed data for monitoring the degradation of Mediterranean lands, it is necessary to extract physical parameters that can be used to describe cover and status of vegetation canopies, to identify important vegetation communities in terms of dominant species, and to discriminate areas already affected from erosion. An experiment which had the Ardeche region (France) as its test site is reported. Details of atmospheric corrections, geocoding of airborne spectrometry data, radiometric data quality, adaptive noise filtering and spectral unmixing are given. The results are presented. They suggest identification capabilities for vegetation and soil related environmental indicators. ESA

INFLIGHT CALIBRATION, PREPROCESSING, AND DATA EVALUATION OF GER 2 IMAGING SPECTROMETRY DATA

F. Lehmann, K. Lehmann, H. Rothfuss, and R. Richter *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 35-42 (For primary document see N94-31853 09-43)

Copyright Avail: CASI HC A02/MF A02

The inflight calibration and preprocessing of the Geophysical Environment Research (GER) imaging spectrometer data is reported. This GER scanner, which covers a spectral range from 0.47 to 2.45 micrometer in 63 bands, was used during the European Imaging Spectrometry Airborne Campaign (EISAC'89). An application for environmental research is reported, in which the spectral response of vegetation cover on and near to unprotected waste deposits was examined for signatures which could be related to the influence of stress caused by the buried material. A further application for exploration and soil/vegetation studies is reported. In both studies, the GER airborne scanner proved to be a useful tool. ESA

POSSIBILITIES OF GER DATA FOR SOIL SURFACE CHARACTERISTICS IN THE ALMADEN AREA

G. F. Epema *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 43-48 (For primary document see N94-31853 09-43)

Copyright Avail: CASI HC A02/MF A02

Geophysical Environment Research (GER) imaging spectrometer data, from the European Imaging Spectroscopy Aircraft Campaign (EISAC'89), of the Almaden area (Spain) were examined for retrieving information on bare soils (with special emphasis on mineralogy). Different parameters describing absorption features are calculated for the image data. Differences in some parameters, like width and depth of absorption dip exist between bare soils. Noise of the GER data makes it difficult to evaluate exactly how much new information this parameter approach adds to traditional image processing techniques. ESA

THE EFFECTS OF VEGETATION ON THE ABILITY TO MAP SOILS USING GERIS DATA

R. J. Murphy and G. Wadge *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 49-55 (For primary document see N94-31853 09-43)

(Contract NERC-F60/G6/12; NERC-GT4/88/GT/99)

Copyright Avail: CASI HC A02/MF A02

Geophysical Environment Research Imaging Spectrometer (GERIS) data from the Almaden (Spain) test site were used to explore the effects that varying proportions of live and dead vegetation cover had on the ability to perform thematic mapping of the geological substrate based on soil types. After calibration to reflectance a least squares unmixing analysis was performed using image endmembers and proportions maps of vegetation and soil/rock components generated. Despite a low signal to noise ratio, three soil/rock and four vegetation endmembers were successfully mapped and validated from field estimates. A quantitative assessment was made of the effects of live and dead vegetation on the ability of the unmixing analysis to distinguish between granite and slate soils. Granite soils were more easily misidentified as slate soils due to vegetation cover than vice versa. Dead vegetation was shown to have a greater impact on soil spectra

than live vegetation. The ability to distinguish between the soils was lost at 50 to 60% vegetation cover. ESA

INVESTIGATION ON CORRECTION MODELS FOR AIRBORNE IMAGING SPECTROMETRY DATA FROM THE EISAC-CAMPAIGN FOR GEOSCIENTIFIC PURPOSES
G. Loercher, J. Henkel, and F. Jaskolla *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 57-60 (For primary document see N94-31853 09-43)
Copyright Avail: CASI HC A01/MF A02

On the base of the airborne spectrometry data from the European Imaging Spectroscopy Aircraft Campaign (EISAC), covering the test sites Almaden (Spain) and Upper Rhine Valley (Germany), investigations were focused on radiometric quality and radiometric correction. Besides an evaluation of the spectrometry data one of the main objectives was to develop different radiometric correction algorithms. The idea was to improve several correction methods for imaging spectrometry that are independent from additional data (for example atmospheric parameters). A further goal was to compare the accuracy of these algorithms and to estimate their applicability on imaging spectrometry data for geoscientific purposes. ESA

MONITORING FERTILIZER APPLICATION BY IMAGING SPECTROMETRY (SOMERSET LEVELS TEST SITE)
A. R. Jones, A. K. Wilson, and S. A. Briggs *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 67-73 (For primary document see N94-31853 09-43)
Copyright Avail: CASI HC A02/MF A02

An experiment, undertaken within the framework of the European Imaging Spectroscopy Aircraft Campaign (EISAC), to evaluate the potential of airborne imaging spectrometry for detecting changes in the spectral response of grasslands associated with controlled applications of nitrogen fertilizer, is described. Different levels of fertilizer applications can be distinguished by the spectral response of the vegetation canopy detected from the airborne data. The use of a linear mixing model for characterizing the vegetation community suggests that changes in the spectral response due to different fertilizer levels are mostly influenced by changes in the physical structure of the canopy. An objective overview of the capabilities of the Moniteq Programmable Multispectral Imager (PMI) system for terrestrial applications is presented and the relevance of advancements in sensor technology for future campaigns is demonstrated. A study, which uses the SAIL canopy reflectance model for evaluating the influence of varying crop parameters, such as Leaf Area Index (LAI) and leaf angle distribution, and external parameters, such as soil reflectance and irradiation conditions, on the theoretical position of the red edge, is reported. Results show that the position of the red edge is independent of soil background, but is largely influenced by LAI. This means that one may get an interaction between two effects of crop stress, namely a lower LAI and a lower chlorophyll content of the leaves. Results show that the solar zenith angle and the atmosphere have only a minor influence on the position of the red edge. During the European Imaging Spectroscopy Aircraft Campaign (EISAC'89), data of a nitrogen experiment at the Somerset test site (UK) were recorded with the Programmable Multispectral Imager (PMI). The analysis of the spectral data depicts a clear spectral shift of the red edge to shorter wavelengths according to decreased nitrogen nutrition of the grassland. Furthermore, different canopy parameters, such as fresh weight, dry matter weight or chlorophyll content were correlated more clearly to the red edge index than to radiance values in individual spectral bands or the normalized difference vegetation index. Airborne Imaging Spectrometry (IS) data of the GERIS (Geophysical Environmental Research (GER) IS) scanner and the Compact Airborne Spectrographic Imager (CASI) sensor were analyzed with regard to their information content concerning plant parameters. The data of the aircraft campaigns were combined with a set of agricultural ground truth and field spectrometry. The preprocessing of the IS data, above all, consists of a conversion of the radiance values into reflectance. The resulting reflectance values of the wavelength region, which contains the most characteristic spectral features of vegetation, the red edge, were parameterized. Two methods (inverted Gaussian fit, second derivative) were used and their advantages and limitations were determined. A strong correlation between the vegetation height of corn and the inflection wavelength of the red edge was found. This correlation was confirmed for different sensors, different methods for extracting the inflection wavelength, different times and different soil backgrounds. The possibility to use data of the future Medium Resolution Imaging Spectrometer (MERIS) sensor for red edge analysis was tested. Although MERIS does not seem very promising for vegetation studies, slight changes of the band setting could drastically improve its performance. ESA

EVALUATION OF FLUORESCENCE LINE IMAGER (FLI) AIRBORNE IMAGING SPECTROMETER DATA FOR ROADSIDE TREE DAMAGE ASSESSMENT
C. Banninger *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 93-99 (For primary document see N94-31853 09-43)
Copyright Avail: CASI HC A02/MF A02

Fluorescence Line Imager (FLI) data acquired along five major transit routes in Austria proved only partly successful in delineating exhaust emission related damage to tree stands bordering the roadways, as determined by changes in the position of the reflectance red edge in the 690 to 750 nm wavelength region defined by the slope-intercept method. The nature and extent of the tree damage present and the shortcomings of the spectral data sets acquired limited the usefulness of FLI data for damage detection in forests lying adjacent to roadways. The information content of airborne imaging spectroscopy data on two different age parameters of oak stands, average stand age and development stage, is assessed. Mean radiance spectra are extracted from 3 by 3 pixel windows and from largest possible homogeneous zones in the stands, both sets of samples fully covering the range of stand ages. Selection of the optimal bands for prediction of stand age parameters is based upon analysis of variance of the spectral response to both stand age parameters. Regression analysis is used to model the relationship between average stand age and radiance in the selected bands. The bands covering the near infrared range are the most suited for both stand age parameters. Approximate SPOT band data are simulated through interpolation of original Geophysical Environment Research (GER) radiances. Simulated SPOT XS3 data yield comparable discriminative power for this purpose in comparison to individual GER channel data. ESA

EVALUATION OF GER- AND FLI-DATA WITH REFERENCE TO FOREST

B. Koch and B. Coenradie *In* ESA, European Imaging Spectroscopy Aircraft Campaign Dec. 1993 p 107-113 (For primary document see N94-31853 09-43)

Copyright Avail: CASI HC A02/MF A02

Geophysical Environment Research (GER) and Fluorescence Line Imager (FLI) data were investigated in order to classify different forest types. The investigations on the data proved that the radiometric performance of the sensors need to be improved for utilization in forestry. The results of the evaluation showed that a high spectral resolution as provided by the GER and FLI instrument gives a better chance to pick the most object conform spectral information. For the classification itself a relatively low number of well positioned bands provided the same separability as a high number. ESA

ALTERNATIVES TO HIERARCHICAL TECHNIQUES IN STEREO CORRELATION Scientific Paper

F. R. Norvelle Mar. 1994 10 p

(AD-A276570; TEC-R-217) Avail: CASI HC A02/MF A01

When digital stereo correlation methods are used to generate elevation data from stereo images of the terrain, the likelihood that the correlation process will be successful throughout the whole of the stereo model can be enhanced significantly by using hierarchical, multi-scale, pyramidal, coarse-to-fine, etc., techniques. One main advantage of these techniques is that the correlation data obtained at a lower resolution in the hierarchical procedure is used to guide and control the correlation process at the next higher resolution and, consequently, the user can be reasonably assured that the correlation process will not get 'lost'. Unfortunately, constraints imposed by results obtained at the lower resolution can also lead to generation of erroneous elevation data in some circumstances. For example, if the terrain is spotted with individual trees, buildings or other structures, the correlation process, when performed on the low resolution images, will include approximations to the heights of these features in the resulting elevation data. These are erroneous elevations compared to the 'bald earth' and their influence will be carried from one step to the next in the hierarchical procedure. The result will be a noisy digital elevation model (DEM) containing approximations to the elevations of trees and structures on the terrain and not just the terrain itself. Noisy elevation data can be minimized as necessary by using non-hierarchical techniques such as full-resolution correlation or the 'Iterative Orthophoto Refinements (IOR)' method. DTIC

REMOTE INFRARED VAPOR DETECTION OF VOLATILE ORGANIC COMPOUNDS Final Report, Oct. 1991 - Sep. 1993

R. T. Kroutil, R. J. Combs, R. B. Knapp, and G. W. Small Sep. 1993 36 p Prepared in cooperation with Ohio Univ., Athens, GA

(AD-A276982; ERDEC-TR-111) Avail: CASI HC A03/MF A01

In many open-air monitoring applications of Fourier transform spectrometry (FTS), the lack of a valid background reference spectrum limits the ability to perform quantitative measurements. Suppression of the broad band detector envelope overcomes this limitation. Interferogram processing provides a means of suppressing the broad band background, while maintaining the target spectral signatures of interest. A combination of interferogram segment selection, digital filtering, and pattern discrimination techniques achieve the background suppression of the variable broad band detector envelope. The spectral band position, width, and strength of the target vapor determine the parameters that are used for background suppression. Interferogram segment selection depends primarily on spectral band width. Digital filter design requires inputs of spectral band position and width. The pattern discrimination techniques compensate for variation in the spectral band contour with signal strength. The FTS in the laboratory and open-air trials demonstrate the utility of the background suppression approach in environmental monitoring of volatile organic compounds. DTIC

SHIPTRACK DATABASE ANALYSIS M.S. Thesis

Douglas E. Mays Dec. 1993 72 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A277228) Avail: CASI HC A04

The radiative characteristics of collected commercial and Navy ship tracks are described through an analysis of AVHRR (Advanced Very High Resolution Radiometer) satellite imagery. The analysis is conducted in a format to show the usefulness of a database approach to processing large amounts of ship track data. Twelve cases are analyzed: 9 commercial ship tracks and 3 Navy ship tracks. Satellite imagery for the above 12 cases was collected during the summer months of 1993 off the western coast of the United States. 306 Navy ship reports are associated with 55 satellite images. This data subset was subdivided and cross-referenced to provide statistical data on Navy track formation when a given report was under favorable track formation conditions. Reflectance signatures of the collected tracks show an increase through the first few hours of track formation. The emittance values of the tracks collected from night-time satellite imagery showed the expected decrease as droplet radius decreases. Nuclear powered vessels showed no evidence of track formation. The utility of database analysis for large datasets of observed ship tracks was demonstrated to be a viable method for future analysis of the 4000+ observed ship tracks in the collected imagery. EVALUATION OF SULFATE AEROSOL OPTICAL DEPTHS OVER THE NORTH ATLANTIC AND COMPARISON WITH SATELLITE OBSERVATIONS

C. M. Berkowitz (Pacific Northwest Lab., Richland, WA.), S. J. Ghan (Pacific Northwest Lab., Richland, WA.), C. M. Benkovitz, R. Wagener, S. Nemesure, and S. E. Schwartz Nov. 1993 8 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994

(Contracts DE-AC02-76CH-00016; DE-AC06-76RL-01830)

(DE94-005457; BNL-49758; PNL-SA-22751; CONF-940115-22) Avail: CASI HC A02/MF A01

It has been postulated that scattering of sunlight by aerosols can significantly reduce the amount of solar energy absorbed by the climate system. Aerosol measurement programs alone cannot provide all the information needed to evaluate the radiative forcing due to anthropogenic aerosols. Thus, comprehensive global-scale aerosol models, properly validated against surface-based and satellite measurements, are a fundamental tool for evaluating the impacts of aerosols on the planetary radiation balance. Analyzed meteorological fields from the European Centre for Medium-Range Weather Forecasts are used to drive a modified version of the PNL Global Chemistry Model, applied to the atmospheric sulfur cycle. The resulting sulfate fields are used to calculate aerosol optical depths, which in turn are compared to estimates of aerosol optical depth based on satellite observations. DOE

AUTOMATED DETECTION OF SHIP TRACKS IN MULTISPECTRAL SATELLITE DATA Progress Report No. 1, 1 Dec. 1993 - 31 Jan. 1994

Mark Fisk 31 Jan. 1994 23 p

(Contract N00014-93-C-0197)

(AD-A276697) Avail: CASI HC A03/MF A01

The objectives of this work are to develop robust ship track detection methods, demonstrate their utility using satellite imagery, and design the framework of an automated ship track detection system for operational use. The approach is to (1) use geographical and multispectral information

to reduce the data stream greatly based on contexts for which ship tracks are physically allowed; (2) optimally enhance satellite images using multispectral signals; (3) apply state-of-the-art edge-detection, dilation and erosion operators in order to find and enhance candidate ship tracks with weak signatures; (4) determine features or parameters that best characterize the higher reflectivity and curvilinearity of ship tracks; (5) apply rule-based and cluster analysis techniques to reduce the data stream to a limited number of subscenes with potential tracks; (6) apply state-of-the-art neural net and statistical discriminant analysis methods as final detection filters; (7) assess detection success and error rates; (8) develop a prototype design of the automated system. The algorithms used here are the kind that have exhibited success on this or similar problems. DTIC

WORLD HEIGHT SYSTEM DEFINITION AND IMPLEMENTATION Final Report, 9 Sep. 1992 - 11 Dec. 1993

Richard H. Rapp and Nagarajan Balasubramania Dec. 1993 34 p

(Contract F19628-92-K-0026)

(AD-A276725; PL-TR-94-2001; AD-E201777) Avail: CASI HC A03/MF A01

Height systems of the world are inconsistent at the + or - 1 m level of accuracy. This report discusses two procedures that attempt to determine an ideal equipotential surface for heights and the connection of regional vertical datums. One method uses 18 stations whose precise geocentric coordinates are known along with the orthometric or mean sea level height with respect to a regional vertical datum. This information is combined with gravity data (for geoid undulation determination) in a general least squares adjustment. The results include the separation between a reference ellipsoid and the ideal (geoid) surface as well as the connection of the regional datums to the geoid. One finds, for example, the origin of the NAVD88 system (U.S.) is 40 + or - 4 cm below the geoid while the ODN (Newlyn) (England) is 26 + or - 23 cm below the geoid. A second procedure to examine the difference between vertical datums used Doppler positioned stations on various vertical drums. Using a degree 360 potential coefficient model, for geoid undulation determination, the separation between several datums was determined. For example, the NN datum used in Germany appears to be 91 cm higher than the reference surface of the ODN (Newlyn) datum used in England. The methods and results described in this report form a foundation for the development of a world height system. DTIC

A MODEL GEOPHYSICS PROGRAM

J. E. Nyquist 1994 8 p Presented at the Symposium on the Application of Geophysics to Environmental and Engineering Problems, Boston, MA, 27-31 Mar. 1994

(Contract DE-AC05-84OR-21400)

(DE94-007415; CONF-940353-3) Avail: CASI HC A02/MF A01

In 1993, I tested a radio-controlled airplane designed by Jim Walker of Brigham Young University for low-elevation aerial photography. Model-air photography retains most of the advantages of standard aerial photography - the photographs can be used to detect lineaments, to map roads and buildings, and to construct stereo pairs to measure topography - and it is far less expensive. Proven applications on the Oak Ridge Reservation include: updating older aerial records to document new construction, using repeated overflights of the same area to capture seasonal changes in vegetation and the effects of major storms, and detecting waste trench boundaries from the color and character of the overlying grass. Aerial photography is only one of many possible applications of radio-controlled aircraft. Currently, I am funded by the Department of Energy's Office of Technology Development to review the state of the art in microavionics, both military and civilian, to determine ways this emerging technology can be used for environmental site characterization. Being particularly interested in geophysical applications, I am also collaborating with electrical engineers at Oak Ridge National Laboratory to design a model plane that will carry a three-component flux-gate magnetometer and a global positioning system, which I hope to test in the spring of 1994. THE EFFECTS OF ALTIMETER SAMPLING CHARACTERISTICS: SOME GEOSAT EXAMPLES Final Report

Michael E. Parke and George Born 20 Jan. 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-92-J-6004)

(AD-A276899; NRL-CR/7320-93-0004) Avail: CASI HC A03

Altimetric satellites have characteristic sampling patterns in both space and time. This paper looks at the distortions of oceanographic and atmospheric signals as seen in geosat altimeter data. Because of the pattern of ground tracks lain down by Geosat, measurements of oceanographic and atmospheric phenomena can be distorted spatially as well as temporally. As a result, phenomena measured by altimetric measurements can appear as propagating waves with both wavelength and wavenumber different from the original phenomena. These changes, if not understood, can result in misinterpretation of results from altimeter data. Also, in some parts of the world, distorted signals satisfy the dispersion relation of other oceanographic waves, or two phenomena can both have the same distorted dispersion relations. A paper describing the results of this research is in preparation and will be submitted to the Journal of Geophysical Research Oceans. DTIC

N94-32249 Los Alamos National Lab., NM.

STATISTICS OF TIME AVERAGED ATMOSPHERIC SCINTILLATION

P. Stroud 1994 11 p Presented at the Society of Photo-Optical Instrumentation Engineers Conference on Intelligent Information Systems, Orlando, FL, 4-8 Apr. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-7405-eng-36)

(DE94-006998; LA-UR-94-691; CONF-940449-1) Avail: CASI HC A03

A formulation has been constructed to recover the statistics of the moving average of the scintillation Strehl from a discrete set of measurements. A program of airborne atmospheric propagation measurements was analyzed to find the correlation function of the relative intensity over displaced propagation paths. The variance in continuous moving averages of the relative intensity was then found in terms of the correlation functions. An empirical formulation of the variance of the continuous moving average of the scintillation Strehl has been constructed. The resulting characterization of the variance of the finite time averaged Strehl ratios is being used to assess the performance of an airborne laser system. DOE

RESEARCH AND APPLICATIONS OF A CANOPY REFLECTANCE MODEL Ph.D. Thesis

Yecheng Wu 1993 151 p

Avail: Univ. Microfilms Order No. DA9317929

Remotely sensed data are commonly used to obtain quantitative information on biophysical characteristics of vegetation for large areas. These biophysical characteristics of vegetation and their spatial and temporal distribution are critical inputs to ecological models that describe the interaction between the land surface and climate, energy balance, and hydrologic and biogeochemical cycle. They can also be used for timber inventory and forest mapping of large areas. In this dissertation, the Li-Strahler canopy reflectance model and multispectral satellite data are used to estimate remotely the parameters of crown size, tree count density, cover, foliage biomass, and total standing biomass for nine coniferous forest stands on a transect of western and central Oregon. The spatial pattern of the test stands in the Oregon transect are statistically analyzed using computer simulated models and field measurements. A modified version of the model is also used to estimate regional forest type, crown size, and density on a stand-by-stand basis of portions of the Sierra Nevada Mountains in California using Landsat TM imagery. Dissert. Abstr.

FROM OPTICS TO RADAR, SPOT AND ERS APPLICATIONS [DE L'OPTIQUE AU RADAR, LES APPLICATIONS DE SPOT ET ERS]

Dec. 1993 443 p In ENGLISH and FRENCH Colloquim held in Paris, France, 10-13 May 1993 Original contains color illustrations

(ISSN 0766-1002)

(ISBN-2-85428-345-7; ETN-94-95852) Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The applications of SPOT and ERS-1 to environmental monitoring, marine and ice mapping, and detecting nonrenewable resources (that is geological

surveys) and renewable resources (forests, crops, and land use) are addressed. In most cases specific case studies are presented and the advantages and disadvantages of SPOT and ERS are discussed. The advantage of the microwave remote sensors on ERS-1 synthetic aperture radar (SAR) is their independence of clouds and daylight, that is, measurement at a given time is always ensured. However, optical satellite data, such as that from SPOT, can not be replaced by SAR data, for example, because of the lower spatial resolution and speckle that characterizes SAR data. Applications of SAR interferometry with ERS-1 are also presented. Image processing techniques are addressed. For individual titles, see N94-32524 through N94-32575.

THE COMPLEMENTARY NATURE OF THE SPOT AND ERS-1 SYSTEMS AND THEIR PLACE IN MAJOR INTERNATIONAL PROGRAMMES

R. Klersy *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 37-42 (For primary document see N94-32523 09-43)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

International programs concerned with the effects and extent of global climate and environmental change are considered. These programs require information at scales that can best be supplied, in many cases, by spaceborne earth observing sensors. The present situation is reviewed with a special emphasis on the complementary contributions of both SPOT and the synthetic aperture radar on board the European Space Agency's (ESA) ERS-1. The technical characteristics relevant to the international programs are reviewed and their respective contributions are evaluated. Two of the programs are examined in more detail in order that the full complementarity of the two systems can be demonstrated. For this purpose the Commission of the European Communities (CEC) monitoring agriculture with remote sensing (MARS) and tropical forest mapping and monitoring (TREES) (tropical ecosystem environment observations by satellite) programs were selected. The great success of the SPOT and ERS-1 satellites is recognized and whether or not the environment community needs a continuation of these programs is discussed. The necessity for institutional environment authorities, who have the financial power to put systems like SPOT and ERS onto a truly operational basis, to define their needs and ensure future satellite systems will produce data that these agencies will be happy to buy, is discussed. It is suggested that environment agencies and departments are integrated into the decision making and financing process. ESA

A study to obtain timely and pertinent information on a glacier lake outburst in the Himalayas (Nepal) by satellite remote sensing means is reported. Image processing methods were used for the analysis of the remote sensing data, especially for the location and quantification of the flood surge trace. The integration of the gained information in a geographic information system (GIS) environment delivered the required knowledge. A prerequisite for the realization of the needs for fast relief is the existence of reference data. These are maps or satellite data of prior date, and especially in high relief digital elevation models (DEM) must be available. Remote sensing data, especially SPOT data, are feasible for the mapping of the accumulation area and the destroyed settlements. For the mapping of trails and bridges higher spatial resolution is needed, which is fulfilled by SPOT panchromatic and in the near future through LANDSAT 6. Further investigations could also give information on risk areas and creation of hazard maps. ESA

A study to show how ERS-1 synthetic aperture radar (SAR) data can be used in coastal studies and which discusses the issue of processing data of different spatial resolution is reported. In geological mapping, a lot of meanders are controlled by structural features, as well as basaltic veins; the morphological contrasts make a detailed lithological mapping possible. In coastal morphology, ERS-1 is able to detect the coast line and main structures such as sand bar like 'cheniers'. In the area of Malmanoury-Karouabo the synergetic use of optical and radar data to monitor coastal changes is discussed. In hydrology, most of the coastal watersheds have particular relations with the ocean, and during the rainy season, coastal swamps are supplied by floods. To understand these relations between all the flows, and where they go, multitemporal data from ERS-1 is analyzed to test which parameters could be detected. Applications of this work are in general mapping, irrigation, and rural planning; in this part of the country, like others in tropical regions, most of the population and human activities are concentrated on coastal zones. A study indicating that the combined use of SPOT multispectral data and ERS-1 synthetic aperture radar (SAR) data can be beneficial for agricultural land use mapping is reported. The study area, the eastern part of the Jutland (Denmark), and available satellite data are described together with the procedure for the coregistration of satellite images and preprocessing. Methods and results of classification are described. It is found that the combination of a SPOT image from the early part of the growing season, where cloud free images are most easily obtained, with SAR images from the later part of the growing season is particularly promising. The implication of this could be the inclusion of the SAR data in, for example, the EEC control schemes for agricultural subsidies or other purposes requiring early delivery of classification results. The obvious benefit is that image acquisition for the middle part of the growing season could be planned and would be independent of the weather conditions. Another benefit is naturally the lower cost of data. It is however also clear that improvements can be added to the described procedures. The per pixel classification method used proved to be far better than anticipated, but it is also clear that a segment based classification method should be better suited for the nature of the SAR data. The history of SPOT and ERS-1 satellites and the use, in environmental management, and mapping are addressed. It is decided that the optimal utilization of ERS may not be found through a rivalry against SPOT or the other sources of geographic information. The history of SPOT has shown that the attempt to make classical maps from SPOT was a failure. SPOT's success was born from a completely new approach of the geographic information market. New products were conceived, taking into account the technical advantages and disadvantages of the satellite and its competitors, and after having clearly identified the fields where these products were clearly preferable. This was, for example, the field of emergency and project mapping, where the SPOT image map appears as one of the best available products. It is suggested that the same kind of approach must be adopted with ERS. It must not be attempted to force applications where ERS is clearly weaker. However, there are many fields where the future of ERS seems to be very bright, and a lot of progress has already been accomplished in the geometric modelization of images, or in application such as forestry. In the field of three dimensional application, radar images may even be a tool more efficient than any other one. The localization is a good example of a possible synergy between SPOT and ERS: ERS may serve as a geometric reference for SPOT space triangulation. In the tropical areas, ERS image maps, despite some unsolved problems concerning the visual aspect of the image, may fill the lack of good georeferenced geographic information. ESA

A study carried out in the Amberieu-Grenoble region, France, which used a geographic information system (GIS) to plan the route to be taken by a motorway is reported. Information on the land use in the proposed region was supplied by SPOT. The image processing is described. Both multispectral and panchromatic images were acquired. The spatial perception supplied by the three dimensional images is a useful tool which needs to be complemented by processing of texture. The SPOT and GIS images were useful in evaluating the evolution of the environment and the economic factors surrounding new motorways. ESA

The ERS data enabled complementation and diversification of the range of mapping products. The adaptation to the 'spacemap' production line of ERS imagery provided an interesting alternative to SPOT imagery in areas where the latter suffers from heavy cloud cover. The satisfactory internal balance of the ERS imagery enabled the validation of a reliable geometric correction model, avoiding in the process the frequent identification problems which arise when it comes to selecting ground control points, and also providing, at a similar cost, performance levels which are identical to SPOT's. The low incidence angle which was selected for ERS was the consequence of noticeably increasing the relief effect. The production of precisely located orthoimages requires the use of highly accurate digital terrain models. In mountain areas, the layover phenomenon frequently results in a loss of information, a dramatic problem in cartographic applications. Despite major efforts in terms of readability improvement, the planimetric use of ERS imagery proved disappointing versus that of SPOT. SPOT did not succeed in replacing aerial photography for the production of topographic maps, but it managed to open a new market: that of spacemaps. In a similar way, ERS does have its limitations, while cartographic requirements still must be met in world regions where optical sensors are inefficient. ESA

SPOT IMAGERY FOR UPDATING LAND COVER INFORMATION OF 1:50,000 NUMERICAL TOPOGRAPHIC MAPS

E. Parmes *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 109-115 (For primary document see N94-32523 09-43)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A method for updating the land cover information of 1:50,000 numerical topographic maps by the map supervised interpretation of SPOT imagery is described. It relies on the fact that more and more of the maps to be updated are in numerical form, and can be used in the numerical analysis of satellite imagery: both for the change detection and for the a priori estimation of correct assignment of changes. The change detection method uses the old numerical map's information to associate the satellite image's spectral classes, derived by an n dimensional histogram clustering method, to the corresponding map classes. The detectability of changes in land cover depend strongly on the features or satellite image channels used, the season of the satellite observations, and the land cover classes present in the area. The method uses the confusions between classpairs, derived from the intersection of the map and the satellite imagery, for the elimination of false change indications, which result from the spectral unseparability of classpairs. A retrospective study of the evolution of Greater Tunis from 1975-1991 and its impact on agricultural areas was carried out using LANDSAT and SPOT images. This study allowed the establishment of images describing the dynamic change of urban areas. A land use map of Greater Tunis in 1990 was realized using SPOT images. This map is the basic source document for updating the urban surveying plan. ERS-1 data was tested mainly for urban classification. The outputs of this study were integrated in to geographic data base systems. ESA

The basic properties of speckle in synthetic aperture radar (SAR) images and their influence on the various parameters are presented. Speckle reduction methods developed to handle these quantities are described. For radiometric channels, a reduction in filtering enables the use of classic algorithms for image processing. The formalisms used to handle variations in magnitude enables speckle reduction methods to be developed which combine the polarimetric, frequency, temporal, and textural aspects. ESA

ASSESSMENT OF REGION-BASED METHODS FOR AUTOMATED SAR/OPTICAL REGISTRATION, ATTRIBUTE EXTRACTION, AND CLASSIFICATION
A. J. Sephton, C. J. Oddy, and A. J. Rye *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 153-164 Prepared in cooperation with MATRA Sep Imagerie et Informatique, Saint Quentinen Yvelines, France (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A number of regional based methods for automated registration of SPOT multispectral and ERS-1 Synthetic Aperture Radar (SAR) images are evaluated and compared in the areas of co-image registration, attribute extraction, and classification. The images were recorded in the Kent area (England). The main scope of the work was directed towards the detection of areas of forestry. The three methods investigated which might be used in an operational system for automated co-image registration and attribute extraction were as follows: post segmentation, region matching method; edge map correlation method; and the 'jiggling' method. While all the techniques are shown to be effective when tested on the SPOT data alone, correlation with the ERS-1 data is found to be dependent on the particular features under observation. Some ideas on how the edge map correlation method may be extended are given. A comparison of the results of the region based, supervised, classification techniques found that the performance attained with the neural network method was more reliable than the statistical technique. Classification accuracies of approximately 90 percent were achieved from a combination of SPOT and ERS-1 data. This overall superiority in performance probably arises from the weaker assumptions made about the underlying nature of the input data for this method. For both the statistical and neural network techniques, a small (approximately 5 percent) improvement in results was found over using the SPOT data alone. By providing pattern data for the neural network based on region attributes rather than at the pixel level, problems of slow training rates were avoided, though of course this technique can only be used where a good segmentation can be produced for the particular scene. ROBUST MULTISOURCE CLASSIFICATION METHOD USING THE MARKOV RANDOM FIELD METHODS [UNE METHODE ROBUSTE DE CLASSIFICATION MULTI-SOURCES UTILISANT DES PROCESSUS ALEATOIRES MARKOVIENS]
Laurent Peytavin, Frank Dansaert, and A. J. Sephton *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 165-173 In FRENCH (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Taking advantage of the complementarity between the optical sensors of SPOT and the Synthetic Aperture Radar (SAR) sensors of ERS-1, new techniques based on Markov random field image models and on neural network driven relaxation were developed and tested for some Earth resources monitoring applications such as forest canopy assessment and urban zone extent evaluation. These techniques make multisource pixel based classification more robust and potentially faster. The first results showed that the multisources regularization induced a nearly total recovery of the forest hidden by the clouds. Compared to a monosource classification on ERS data the classification precision is improved. Compared to a microwave classification on SPOT data the results are significantly improved as soon as the local cloud cover rate is above 5 percent. ESA

TECHNIQUE OF ERS-1 IMAGE PROCESSING IN ASSOCIATION WITH SPOT DATA [TECHNIQUE DE TRAITEMENT DES IMAGES ERS 1 EN ASSOCIATION AVEC DES DONNEES SPOT]
Maylis Galaup, Jochen Harms, and Jean-Guilhem Cailton *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 175-177 In FRENCH Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Within the pilot project, 'Integration of ERS-1 data into the European project of agriculture statistics,' new techniques of image classification were tested. The automatic segmentation of optical data is used as a base for the field (classifies) applied to the ERS-1 data. An initial analysis of ERS-1 images by photointerpretation and application of classical optical image processing techniques lead to research into processing methods which are more adapted to radar images. Three of these methods were tested on the region of Seville (Spain). ESA

AIRBORNE SAR AS A COMPLEMENT TO SPOT HRV IN LAND-COVER CLASSIFICATION: THE USE OF NORMALIZATION AND PRINCIPAL COMPONENTS ANALYSIS
Marvilyn P. Palaganas *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 179-190 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A study which investigates the effect of the inclusion of Synthetic Aperture Radar (SAR) data to SPOT High Resolution Visible (HRV) data in the overall classification accuracy in delineating general land cover types is reported. The SPOT HRV sensor is a 'pushbroom' scanner. The SAR data was acquired on board the STAR aircraft in digital format and recorded on high density digital tape. Details of the image registration, filtering, texture transform, SAR and optical data integration, classification, and ground verification, are given. It was found that an increased overall accuracy was attained in the combination of the two data sets. However, a comparison of the classification accuracies of the specific land cover types varied with different methods used in the integration of the radar data to the optical data in the digital classification. ESA

FUSION OF MULTISPECTRAL (XS) AND PANCHROMATIC (P) SPOT IMAGES AND RADAR IMAGES [FUSION D'IMAGES SPOT MULTISPECTRALE (XS) ET PANCHROMATIQUE (P), ET D'IMAGES RADAR]

Marc Mangolini, Thierry Ranchin, and Lucien Wald *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 199-209 In FRENCH (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A way of increasing the spatial resolution of SPOT multispectral images (XS) using the corresponding panchromatic image (P) is presented, as well as the injection of information derived from ERS-1 into the former images. Existing methods for merging P and XS are analyzed before presenting a new method which aims at simulating 10 m resolution multispectral images that contain the same spectral information as the XS images. The following step consists of injecting detectable objects of the ERS-1 image into the SPOT images. These two fusion steps are both implemented using multiresolution analysis and the wavelet transform. Although the present method might be refined, it already provides very interesting results. ESA

SHIP TRAFFIC MONITORING AND OIL SPILL DETECTION USING THE ERS-1 SAR
Terje Wahl, Tom Anderssen, Knut Eldhuset, and Aage Skoeelv *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 211-220 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A fast processing and distribution chain for ERS-1 Synthetic Aperture Radar (SAR) images was developed in Norway. Large quantities of ERS-1 images were analyzed to assess the capability of ERS-1 for ship detection, ship wake imaging, and oil slick detection. Automatic detection and analysis of ships and ship wakes using the 30 m resolution SAR Fast Delivery product was demonstrated. For oil spill detection use was made of 100 m resolution images of high radiometric quality. Ships above 120 m length are generally seen in ERS-1 images under most weather conditions. Ships smaller than 100 m may sometimes become practically invisible in the SAR images because of the strong backscatter from the sea surface at some wind speed (an effect due to the steep incidence angle of ERS-1). Ship wake signatures in ERS-1 images are very similar to those in SEASAT images. The most frequent wake feature is the dark turbulent wake. Several confirmed observations of oil slicks were reported. At low wind speed, natural surface slicks may in some cases be classified as oil slicks. Due to very strong winds, no oil slick signatures were seen in ERS-1 images from the wrecked oil tanker 'Braer'. ESA

N94-32543 MATRA Marconi Space (England).
SAR IMAGE FEATURE EXTRACTION SYSTEM: A PRE-OPERATIONAL APPLICATION OF ERS-1 SAR
I. J. Green, F. G. Sawyer, and S. B. Dunster *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 221-230 Sponsored by British National Space Centre Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The Synthetic Aperture Radar (SAR) Image Feature Extraction System (SIFES), which was developed to demonstrate the capabilities of an end to end SAR system, is described. The first application to be demonstrated by the SIFES facility is ship traffic monitoring; for this, SIFES will be operated in a Ship Detection Workstation (SDWS) mode to extract information about shipping imaged by SAR. The workstation contains a processing chain which was assembled from algorithms developed during the project. These enable the automatic processing of input SAR image data to extract shipping information. The workstation has a powerful processing capability to rapidly execute these algorithms. Results are displayed as the data is processed allowing the operator to change algorithm parameters to optimize system performance. SAR data throughput is extremely large. The SDWS contains careful data management and storage which is required for efficient and rapid processing. The output product from the SDWS is a map of shipping in the coverage area. This can be sent electronically to end users of the information. An overview of the SDWS including a description of the hardware system, software, and algorithm chain, is presented. Results from the system are also presented and assessed. Recommendations for future operational SAR system applications are given. ESA

ALMAZ MARINE APPLICATIONS [LES APPLICATIONS MARINES D'ALMAZ]
E. Xenofontov *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 231-235 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Details of the Synthetic Aperture Radar (SAR) carried onboard Almaz-1 are given, and its advantages when compared to instruments of visible and infrared ranges are addressed. An assessment of experiments within the Ocean 1 program are assessed. It is noted that the possibility of recording the atmosphere and ocean surface processes is connected with the changes of sea surface scattering properties due to these processes. The main contribution into the sea surface radioscattering is made by short gravity capillary waves from 1 to 30 cm long, which exist practically everywhere on the ocean surface. To interpret radar images correctly it is necessary to understand the processes of obtaining images from SAR. These processes are addressed, and examples of interpreting ocean surface radar images are given. These examples concern the following: surface waves and swell; internal waves; currents, circulations, and whirl; fronts and frontal zones; underwater topography; oil pollutions; ship traces; and sea ice and icebergs. ESA

THE USE OF SPOT AND ERS-1 IMAGES TO MAP THE ERUPTION OF NEVADO SABANCAYA (PROVINCE OF AREQUIPA, SOUTH PERU) AND EVALUATE ASSOCIATED RISKS [SUIVI DE L'ERUPTION DE NEVADO SABANCAYA (PROVINCE D'AREQUIPA, SUD PEROU) PAR IMAGES SPOT ET ERS1 ET CARTOGRAPHIE ET EVALUATION DES RISQUES ASSOCIES]
R. Guillande, D. Huaman, J. Chorowicz, J. C. Thouret, and F. LeGuern *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 247-250 In FRENCH Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The eruption of the Nevado Sabancaya, which began a phreatomagnetic eruptive process on 28 May 1990 after 4 years of weak fumorallic and seismic activity, is addressed. The eruption had been foreseen by comparing images of Jul. 1986 and 1989 that showed differences in the ice cap within the crater. The eruption was monitored since Jun. 1990 by acquisition of six SPOT images. The images proved to be very helpful to analyze the impact on the regional environment, the evolution of the crater, and also the neighboring glaciers where lahars were generated. Other volcanological techniques and field observations were used to control satellite observation. Both field and satellite techniques complete each other. The lack of resources of the local geophysicists was partially compensated by remote analysis of SPOT images in France. ERS-1 images were acquired but are not available yet because of malfunctioning of the Cotopaxi reception station. Geometric simulation of Synthetic Aperture Radar (SAR) images were produced to determine whether or not deformation observed on the volcano will be visible on radar images and to help programming of the next

images in order to have the maximum information on the strategic area of the volcano. The delay of availability of SPOT as well as ERS images seems to be the major inconvenience in the use of satellite images for monitoring erupting volcanoes. This is less important in the case of monitoring of sleepy but potentially dangerous volcanoes. Satellite observation coupled with seismic monitoring transmitted by ARGOS beacons could be a minimal system for monitoring the hundreds of potentially dangerous volcanoes throughout the world. ESA

An appraisal of the relative geological mapping performance of the most widely available remotely sensed data was carried out. A fracturing study at a local scale of a grinitic body is presented. A comparison of these results with those derived from a previous regional scale analysis, points out that the best data are not the same at the two scales. This is not linked to sensors resolution but to the nature of the geological objects that are pointed out at regional and local scales. The best results were obtained with merged SEASAT-SPOT imagery and with combined LANDSAT Thematic Mapper (TM)-SPOT panchromatic data, respectively. ESA

An optimal synergism procedure was worked out combining SPOT information with radar information especially for geological applications. Combinations of data from four different sensors were examined: ERS-1 radar and SPOT multispectral (XS); SPOT and Shuttle Imaging Radar (SIR A); SPOT and SIR B; and LANDSAT multispectral scanner and airborne Synthetic Aperture Radar (SAR). The data was obtained from four different study areas, the details of which are given. An HIS transformation was performed on SPOT XS and LANDSAT data resulting in a color enhancement making rock differentiation in the areas possible. To obtain the full benefit of the spectral information from SPOT and the textural and pattern information from radar (ERS-1, SIR A, SIR B, and airborne radar), a synergistic image was produced using the hue and saturation information from SPOT/LANDSAT and the intensity values from radar data. On the basis of a comparison of single radar or single SPOT data with synergistic SPOT radar data an evaluation was made regarding mapping of geologic lithologic boundaries and recognition of structural features like faults and folding. Information from SPOT and the satellite radar are found to be complementary. ESA

A multiscale approach for morphostructural interpretation is addressed. The following methodology was assessed: compared analysis of all imagery available in the studied area at different scales and various wavelenghts including radar data, where the drainage pattern is extracted and anomalies underlined; these anomalies are also enhanced by the drainage patterns given by topographic maps permitting comparisons and validation. This methodology was applied to morphostructural studies at various scales in several test areas. In the small 1 by 10 km size area of Pezenas (southern France), SPOT and airborne ESAR German radar scenes were used to evidence new faults: some of them are potential structural guides for oil prospecting. From a LANDSAT Thematic Mapper scene combined with a Synthetic Aperture Radar (SAR) ERS-1 scene of Erzincan (Turkey) in a 100 by 100 km size mountainous area, the northeastern segment of the Ovacik fault was analyzed. Drainage pattern anomalies and offsets have given the amount of recent strike slip motion along the fault. In these examples, drainage pattern anomalies are closely related to the regional tectonic framework: according to its high sensibility to slope effects, the radar tool is convenient for drainage pattern analysis and morphostructural work. In order to separate the effects of the different tectonic and climatic processes on the shapes of desert piedmonts, a modified conic equation was fitted to digital topographic data for individual alluvial fans in Death Valley (California, U.S.). The topographic data were obtained from a SPOT panchromatic stereo pair and from the airborne interferometric SAR (Synthetic Aperture Radar) (TOPSAR). The conic fit allows parameters for the epex position, slope, and radial curvature to be compared with unit age, uplift rate, and climatic conditions. Preliminary results indicate that slope flattens with age and radial curvature is concave up, but decreases with age. Work is continuing on correlation of fit residuals and apex position with fan unit age. This information will help in the determination of tectonic uplift rates and the climatic history of the western U.S. ERS-1 SAR images were used to study an area of western China where a large strike slip fault crosses a series of alluvial fans and stream valleys. Previous analysis of SPOT panchromatic images of the area shows that offsets fans and streams can be recognized. Measurement of the rate of motion of this fault will help in the overall model of deformation of the Asian tectonic plate in response to the collision of the Indian plate. ESA

An experimental survey, a part of a pilot project aiming to evaluate geological interest of ERS Synthetic Aperture Radar (SAR) data in specific conditions, 10 m alteritic formations masking the substratum, is reported. Two SAR images were processed and visually interpreted. These images were acquired under different conditions: ascending and descending mode, May and Sep., after a 10 day rainy period and 10 days without rain. The two interpretations are quite different. The May image reveals a quantity of

valuable structural informations outlining the different units mapped by drilling, scattered field observations, geochemistry, geophysics and optical remote sensing. Particularly, a buried granitic body, well mapped by gravimetry is enhanced on the surface through radar discontinuities. On the other hand, the information outlined by the Sep. second image is quite null as far as geology is concerned, which is important for hydrography network, roads, villages and forests. As a preliminary conclusion it appears radar imagery is quite a valuable tool for structural analysis in the plateau des Mauges conditions but acquisition characteristics have a great influence on the geological interpretation capacity. It appears absolutely necessary, more than in optical remote sensing, to optimize selection of appropriate data and all weather radar capacity make this possible. ESA

The evolution of the mapping of natural risks is reported. An experiment to evaluate the Synthetic Aperture Radar (SAR) capacity for landslides mapping over the Chicamocha Valley (Columbia), which has been proposed and accepted for ERS-1 and the Japanese JERS, is addressed. A GIS (Geographic Information System) was prepared with SPOT and LANDSAT data, Digital Elevation Models (DEM) and derivated files, and a geological map. Some methodological aspects were studied such as simulation of stereopairs of airborne SAR over Taiwan, but realization of the Chicamocha Valley study is still pending, due to lack of data. For this reason a substitute test site was chosen in Boulc (France), where, till now geodesic space measurement have been realized with the DORIS (Doppler Orbitography and Radiopositioning Integrated by Satellite) system. The surface state of subpolar glaciers were studied on the basis of combined SPOT and ERS-1 data. The approximately 64 sq km training zone of the Brogger and Loven glaciers is situated in the northwestern Spitsbergen, 79 deg. north. The SPOT data present extensive shaded zones arising from the combination of low Sun elevation (7 to 15 deg) and mountainous topography. The SPOT reflectance values were corrected using the slope orientation and dip parameters from the Digital Elevation Model (DEM) combined with the corresponding Sun elevation and azimuth. The reflectances of the shaded and illuminated zones were restored to a new image based on the XS1 versus XS3 bidimensional histogram. This new image provides a map of the different surface states of the glacier which is homogeneous in both the shaded and illuminated zones. The ERS-1 data are not influenced by the Sun's position but the incidence angle gives rise to geometric distortions. An attempt was made to reduce the speckle by using low pass filters and filters based on contrast and morphological criterion. A new reconstruction morphological filter, which reduces significantly the speckle while preserving the structure of the original image, was developed. Geometrical corrections were done using the DEM. The comparison of processed ERS-1 image with the DEM shows that the ERS-1 values of the glacier surfaces depend mainly on the dip angle of the ground surface and allows one to reconstruct partial DEM of glacier surfaces from ERS-1 data. Assessment of combination and complementarity of SPOT and ERS-1 SAR (Synthetic Aperture Radar) data was performed in a study on tropical vegetation mapping and mangrove dynamic monitoring in French Guiana. Three channels SPOT and two ERS-1 images recorded at 23 and 35 deg of incidence angle were used jointly in a supervised classification. Results show that the main information comes from the SPOT data, nevertheless, in some cases, ERS-1 data appear very helpful for discriminating vegetation classes. On the other hand, ERS-1 data cannot be used alone with satisfactory results. The utilization of ERS-1 SAR data, in tropical vegetation studies, necessarily implies the combination of multitemporal data and multispectral data including available other SAR data (the Japanese JERS-1) and optical data (SPOT, LANDSAT). In the frame of the joint ESA Commission of the European Communities (CEC) TREES (Tropical Ecosystem Environment observation by Satellite) project, ERS-1 Synthetic Aperture Radar (SAR) data of West Africa are evaluated on their information content for mapping tropical ecosystems. A supervised classification methodology to exploit both the tonal and textural characteristics of ERS-1 SAR imagery is described. Supervised classifications are carried out on a multitemporal ERS-1 SAR data set and a monotemporal SPOT panchromatic data set. The resulting classifications are compared on the basis of their accuracy for the discrimination at the forest/nonforest level. It was found that the classification accuracies for the ERS-1 SAR

data (65 percent) are inferior to those obtained from the SPOT panchromatic data (95 percent). Factors limiting the results obtained are discussed for both sensors and possible analysis improvements suggested. ESA

Synthetic Aperture Radar (SAR) data were used to assess soil moisture. The project was carried out for the Obra river valley (Poland) during the season of 1992. The study area was covered by grassland with the variety of soil types and soil water conditions. Simultaneously to ERS-1 overpass the soil moisture in the 20 ground points, for different soil layers and soil water potential representing the dielectric constant of soils, was measured. Three successive SAR images were taken to make the color composite on which the ground observations were located. The value of nine pixels were taken as the average for further investigations of correlation with ground measurements. The point of ground observation was located in the middle of each block of nine pixels. The first investigation shows that there is a relation between the microwave signal recorded by SAR and soil moisture in the depth of 0 to 10 cm. ESA

SYNERGY OF THERMAL INFRARED AND MICROWAVE REMOTE SENSING FOR EVAPORATION ESTIMATION
O. Taconet, A. Vidal, F. Rahman, L. Rakotoarivony, S. Laguette, and D. Vidal-Madjar *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 373-383 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The principles of thermal infrared/microwave synergy for determination of surface evaporation are addressed. This synergy was studied during Mac Europe/Orgeval 91 experiment when simultaneous high resolution optical and microwave AIRSAR images were taken over wheat fields. Concommittance of acquisition is not sufficient to have images interpretable in the different bands. Optical images with minority of cumulus are adequate to obtain vegetation index but could not be used for thermal band due to complex feedbacks between vegetation mass transfers and variable solar sky condition. Use of thermal band needs stable clear or cloudy sky. Direct 1-layer models of evaporation are still satisfactory during the Orgeval experiment. The synergy for the estimation of vegetation structure (foliage density and aerodynamical displacement height) was studied. Optical vegetation index and vegetation water content from cloud models are used to derive Leaf Area Index (LAI) over wheat. Microwave derivations of LAI compared to the optical ones are too highly variable to be reliable to derive evaporation, especially for wheat canopies with low cover as encountered after the maturation. MONITORING LANDSURFACE CHARACTERISTICS IN NIGER USING COMPLEMENTARY SPOT AND ERS-1 SAR DATA
Gerrit F. Epema and Peter J. vanOevelen *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 385-396 Sponsored in part by Commission of the European Communities and Beleidscommissie Remote Sensing Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

In the Sahelian zone of Niger, possibilities of SPOT and ERS-1 Synthetic Aperture Radar (SAR) for determining surface characteristics were examined. Preliminary results show that SPOT dry season data are good to discriminate bare surfaces with differences in iron content. Multitemporal SPOT data during the rainy season make it possible to discriminate a range of vegetation and crop types in this area and to follow their development. ERS-1 SAR information is very difficult to use separately in this area. A more integrated and synergetic approach in combination with optical sensors and some field check is necessary. Because the variation, both spatially and spectrally, within and between some classes is gradual for both SPOT and ERS-1 SAR, classification will remain difficult. ESA

As part of the European Monitoring the Agriculture by Remote Sensing (MARS) project, whose objective is to provide regular information on crops in Europe, radar data from two complementary programs were evaluated to see how they may overcome some of the problems posed by seasonal cloudiness (which can upset the observation calendars and thus subsequent exploitation of the data). The radar data evaluated came from an airborne E-SAR radar operating in the X channel, and the ERS-1 ESA pilot project. The study areas were Great Driffield (U.K.) and La Beauce (France). An area survey provided reference data for 15 sites, in order to compare the classification performances for several data sets, including just SPOT data, a temporal series of ERS-1 data, and coupled SPOT/radar data using either the C channel from ERS-1 or the X channel of E-SAR. Two possibilities of using radar data for crop discrimination were evaluated: either a procedure mixing optical and radar data that aims at improving the optical data at the lowest possible cost by adding data from one or more radar images; or a procedure discarding the optical domain, using only a multitemporal series of radar images. The results show the interest and the limits of the two options. A mixed procedure would make it possible to refine surface estimates for certain groups of crops, for example Summer crops. The X channel, which was only tested in airborne mode, led to significant performance. The multitemporal ERS-1 data provided part of the required crop inventory objectives, but filtering techniques are being developed that might improve the performance of such data and it might confirm the potential of ERS-1 data to be substituted in case of cloudy conditions. Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The relation between ground organization surface topography and forest cover was studied using remote sensing images to extrapolate ground knowledge. Two types of hill were studied in Yaoundy (Cameroon): an average inselberg hill with thin organic soil layer, and a low hill with a ferritic organization. The morphological characteristics of these two types of hill were extracted from Digital Terrain Models (DTM), and two SPOT images and a Spaceborne Imaging Radar (SIR A) image were analyzed to evaluate their capabilities of discriminating these characters and their spatial extension. It was found that a thematic map could be produced by analyzing the texture on the SIR A image and superimposing the information obtained from the SPOT image. To analyze relief on a local level, SIR A did not enable a better interpretation than SPOT. However, extrapolation of morphological characteristics for regional mapping is made possible by SIR A, in this case. It is thought that use of ERS-1 would confirm these conclusions. ESA

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A hydrological space observatory was implemented on a small agricultural watershed in the center of Brittany. The main objective is to study the usefulness of the ERS-1 Synthetic Aperture Radar (SAR) images for water resources monitoring. During 1992, a great number of ERS-1 images were acquired together with extensive ground truth. It is shown, as one of preliminary results, that thanks to its all weather capacity to obtain time series of data, the SAR images can be used in conjunction with SPOT data to map the soil occupation. ESA

LAND COVER CHANGE DETECTION WITH ERS-1 DATA AND DATA FROM OTHER REMOTE SENSING SATELLITES. EXAMPLE: THE DELTA OF THE RIVER EBRO (SPAIN)

Jochen Harms *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 445-446 Original contains color illustrations (For primary document see N94-32523 09-43)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Information was acquired with the help of 'traditional means' (SPOT, topo-maps, Corine Land Cover) and stored in a database. Different SPOT images were classified to receive information on the quantity and quality of land cover changes in the past years (1985-1992). Recent SPOT images are used together with ERS-1 images to understand the content of the radar signal. Therefore the ERS-1 images are rectified on a common base with the SPOT images. Different filtering procedures are used to reduce the speckle noise in the radar images. Following this, different techniques are used to classify the radar images: supervised and unsupervised classification of mono and multitemporal ERS-1 images; segmentation of mono and multitemporal ERS-1 images and classification on the base of this segmentation. Additionally, SPOT images are merged with ERS-1 images and classified with different techniques (for example principal components). ERS-1 images will be used to detect land cover changes. Images will be merged to identify the advantages and limitations of C band radar. First results of the project indicate the advantage of using radar data in combination with optical data. The technique of automatic classification by segmentation at field based classification was identified as the most promising technique for change detection measurements in coastal regions. ESA

ERS-1 SAR AND OPTICAL DATA FOR LAND USE/LAND COVER MAPPING: A CASE STUDY IN A SAVANNAH ZONE OF GUINEA

J. F. Dallemand, J. Lichtenegger, V. Kaufmann, B. Barry, N. Diaby, and P. Reichert *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 447-456 (For primary document see N94-32523 09-43)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Results of an assessment of the use of ERS-1 Synthetic Aperture Radar (SAR) data for land use/land cover mapping in a savannah zone of West Africa are presented. Optical data (SPOT, LANDSAT Thematic Mapper (TM)) were compared with microwave data (Spaceborne Imaging Radar (SIR A), ERS-1). LANDSAT TM data were initially geocoded with a Digital Terrain Model (DTM) and then registered with ERS-1 data. Multispectral SPOT data were interpreted at 1:100,000 and 1:50,000 scale. Standard and adaptive SAR filters were compared. Two methods of optical/microwave data integration were tested: intensity hue saturation transformation and optical/radar color combination. It appeared that identification of land use classes was not satisfactory using ERS-1 data of a single date. Better results were obtained in the case of a multitemporal SAR approach and especially when combining dry season optical data with rainy season SAR data. In this latter case it becomes possible to define more detailed visual interpretation keys. The complementarity of SPOT multispectral (XS) and ERS-1 SAR data for flooded rice fields monitoring is very promising due to the strong backscatter variations during the crop cycle. ESA

SAR INTERFEROMETRY WITH ERS-1

S. N. Coulson, G. A. Solaas, F. Rocca, C. Prati, A. Monti-Guarnieri, P. Hartl, M. Reich, and C. Werner *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 457-472 Original contains color illustrations (For primary document see N94-32523 09-43)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Activities and results to date within the framework of an ESA mission working group ERS-1 FRINGE, which exploits the techniques of Interferometric Synthetic Aperture Radar (INSAR) with ERS-1 for precise measurement of the Earth's surface topography and movement, are described. It was found that INSAR provides accurate values of surface height with spatial resolution and independent of cloud cover. Preliminary results indicate that terrain height errors of less than 10 m are achievable with ERS-1. The capability of ERS-1 to measure cm scale movement of surface features through differential INSAR was demonstrated. The technique of differential INSAR opens the door to many new potential SAR applications including crustal dynamics, fault slip detection and volcanology. ESA

Differential interferometry effects over agricultural surfaces were obtained using SEASAT data. These effects were attributed to soil swelling following irrigation. These effects were studied using ERS-1 data with the goal of assessing the usefulness of interferometric products for crop classification. By interferometric product, is understood not only 'non topographic' phase differences, but also additional information such as coherence. A site was

selected which allows opportunistic differential interferometry through a combination of close orbital tracks and a moderate topography. On this site of more than 300,000 sq km several hundreds of agricultural units were selected. The information gathered on each unit was the amplitudes of the images of the pair, the coherence of the pair and the difference of phase which cannot be explained by orbital or topographic effects. Several definitions of coherence were tested from the point of view of classification power, computational load and convergence speed. One of them seems more interesting than the standard one. A simple double target modelization, was studied to separate the uncoherent part of a pixel from the coherent one. The existence of targets able to change their amplitude while keeping a high degree of coherence is a critical point for the inversion of such a model. Although more focused studies are now envisioned on sites where ground truth is available, preliminary results show the high potential of differential interferometry for crop classification. ESA

The ERS-1 Synthetic Aperture Radar (SAR) demonstrated that it is possible to measure high resolution topography over large areas using interferometry with repeat orbit data sets. Given that the ERS-1 orbit is known with high precision, an automatic system for generation of interferograms is presented. Least squares estimation using ground control points provides an accurate method for determining the precise interferometric baseline. The system parameters which affect the accuracy of the Digital Elevation Models (DEM's) are errors in the interferometric baseline, decorrelation caused by baseline separation, thermal noise, and surface change. An adaptive filter based on the local interferometric coherence was developed to improve phase unwrapping of the interferogram. Final accuracies of the DEM's generated for single scene pairs in Alaska (U.S.) and Bonn (Germany) are on the order of 5 to 10 m. ESA

DEVELOPMENTS IN ERS-1 SAR INTERFEROMETRY: USE OF THE SPECTRAL SHIFT
F. Gatelli, A. Monti-Guarnieri, F. Parizzi, P. Pasquali, C. Prati, and F. Rocca *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 491-500 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

Synthetic Aperture Radar (SAR) surveys from separate passes shows relative shifts of the ground wavenumber spectra that depend on the local slope. The exploitation of the spectral shift for different applications is discussed: generation of 'low noise' interferograms benefiting phase unwrapping; generation of quick look interferograms; and decorrelation reduction by means of Tunable Interferometric SAR (TINSAR) systems. DIFFERENTIAL INTERFEROMETRY STUDY OF AN EARTHQUAKE [ETUDE DU SITE D'UN TREMBLEMENT DE TERRE PAR INTERFEROMETRIE DIFFERENTIELLE]
D. Massonnet, M. Rossi, F. Adragna, and C. Carmona *In its* From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 501-509 Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

ERS-1 satellite images of the Los Angeles (California, U.S.) region taken on four separate dates surrounding the Landers earthquake of 28 Jun. 1992, were analyzed to verify the feasibility of mapping crustal movements with differential interferometry. The results obtained prove that it is possible to obtain interferometric fringes despite the elapsed 105 days between the data takes of the most interesting pair of images. The combination of an image pair spanning the earthquake with a Digital Elevation Model (DEM) proves the possibility of determining the orbital positions of the satellite when taking the images without the help of any artificial ground target (image locking technique) and without working with exceptionally close orbits, despite the relatively rough topography of the site. The result is a map of the coseismic moves caused by the earthquake. This map matches closely the geophysical modelization obtained. ESA

PRECISION AND LEVEL OF ARTEFACTS IN THE COMPUTATION OF DIGITAL TERRAIN MODELS BY INTERFEROMETRY [PRECISION ET NIVEAU D'ARTEFACTS DANS LES CALCULS DE MODELES NUMERIQUES DE TERRAIN PAR INTERFEROMETRIE]
D. Massonnet, F. Perlant, and T. Rabaute *In its* From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 511-523 Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The future of Digital Elevation Model (DEM) extraction by radar interferometry, is discussed. This depends critically on the amount of phase artefact due to terrain surface phase changes or atmospheric depth variations and also on the importance of decorrelation between scenes, due to target modifications or to intertrack distance. Some of these, such as the statistics of the intertrack distance, may be obtained through the features of the system, and be improved by multiple scene acquisition. Other artefacts, either linked to atmospheric conditions or specific target behavior, are much more difficult to characterize. A statistical approach for the latter is proposed and a large surface of interferometric data is processed in order to gather an experimental assessment of the amount of artefact occurring with varying conditions of observation related to intertrack distance, terrain nature, terrain shape and time elapsed between observations. According to their spatial signatures, artefacts may be spotted visually (for instance in the case of a loss of coherence over a water surface) or only after the DEM has been completed (in the case of low frequency atmospheric depth variations). In any case, the comparison of the interferometric DEM and of a DEM obtained by standard techniques is the ultimate tool. Several examples of such a comparison are shown. ESA

An experiment to show that Interferometric Synthetic Aperture Radar (INSAR) plays an important role in generating Digital Terrain Models (DTM's) and in detecting small changes in the Earth's surface during two successive orbits is presented. The experiment was carried out in Bonn (Germany) in March 1992, with a three day repetition orbit. A description of the fieldwork, the deployment of corner reflectors, the measurements and the data analysis is given. Also some further investigations concerning the capability of the SAR for absolute height and spatial resolution were carried out. Another experiment in Naples (Italy) performed using the 35 day repetition orbit of ERS-1 is also addressed. Using ascending and descending orbits, the movements linked to the relaxation phase were measured. ESA

THE PROCESSING TECHNOLOGY AND SOME APPLICATIONS OF ALMAZ-1 DATA
I. V. Elizavetin *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 535-540 (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

The 'Almaz' space program, developed on the base of unique space platform for accommodation of a vast instrument set for the Earth remote sensing is addressed. The remote sensing capacity is used for exploration and practical monitoring of natural resources in various spectrum ranges of electromagnetic waves for the sake of ecology, agriculture, forestry, geology, cartography and other fields of a national economy. The main

observation system onboard Almaz spacecraft, represented by high resolution Synthetic Aperture Radar (SAR) for all weather, round the clock radar survey of land and ocean surface, is addressed. Almaz-1 spacecraft was launched into the Earth's orbit on Mar. 31 1991. The technology of image processing, and the application of Almaz-1 data for stereomapping and interferometric investigations are discussed. ESA

QUANTITATIVE ANALYSIS OF WOODY VEGETATION IN SOUDANO-SAHALIAN REGION. TEXTURAL APPROACH (APPLICATION TO A BURKINA FASO REGION) [ESTIMATION QUANTITATIVE DE LA VEGETATION LIGNUEUSE EN REGION SOUDANO-SAHELIENNE. APPROCHE TEXTURALE (APPLICATION A UNE REGION DU BURKINA FASO)]
K. Djaroudib *In* CNES, From Optics to Radar, SPOT, and ERS Applications Dec. 1993 p 541-552 In FRENCH Prepared in cooperation with Louvain Univ, Belgium Original contains color illustrations (For primary document see N94-32523 09-43)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vauquelin, 31100 Toulouse, France)

A study which showed the contribution of textural information in the quantitative analysis of woody biomass in remotely sensed data is presented. The idea was to establish correlations between measured radiations or their combinations, vegetation indexes for example, and parameters characterizing the vegetal cover such as overlapping amount relative to the soil or leaf area index. However, the influence of some covers to spectral indexes in precise seasons risk to give doubtful results. In Soudano-Sahalian region, during the rainy season, the spectral signature of herbaceous stratum in a savanna with trees, is predominant for vegetation index calculations. This makes the spectral approach doubtful at this vegetative stage. Another element which should characterize the state of a cover and will be complementary to its spectral information, is its spatial arrangement or its texture. High resolution spatial data reinforce this idea and permit to distinguish different textures of a cover: a black blob on panchromatic SPOT data represents a trees or a group of trees. Thus two different overlapping areas are presented according to two different textures and the hypothesis is that a relation exists between overlapping density of trees and their spatial arrangement. This arrangement was quantified thanks to the textural parameters calculation derived from cooccurrence matrices, and their correlations with other parameters characterizing the vegetal cover were tested. Results are presented. ESA

EARTH OBSERVATIONAL RESEARCH USING MULTISTAGE EOS-LIKE DATA Final Report, 1 Aug. 1986 - 31 May 1994
C. J. Johannsen and D. A. Landgrebe 31 May 1994 22 p
(Grant NAGw-925)
(NASA-CR-195833; NAS 1.26:195833) Avail: CASI HC A03/MF A01

This grant was funded as a part of a program in which both research and educational impact were intended. Research work under this grant is directed at the understanding and use of future hyperspectral data such as that from imaging spectrometers. Specifically, the objectives of the work were: to prepare suitable means for analyzing data from sensors which have large numbers of spectral bands, to advance the fundamental understanding of the manner in which soils and vegetative materials reflect high spectral resolution optical wavelength radiation, and to maximize the impact of the results on the educational community. Over the life of the grant, the work has thus involved basic earth science research and information system technique understanding and development in a mutually supportive way. However, during the later years it became necessary to focus the work primarily on the first and last areas, due to a steadily decreasing level of effort. Derived from text

(PB94-137502; SP-RAPP-1993:36) Avail: CASI HC A03

The report presents the progress, status and goals of the Chinese national solar energy programs since 1970's. It applies specially to solar water heating, solar drying, passive solar, solar cookers, and solar photovoltaics. In China, an expert team has been organized, a number of technology development centers for new and renewable sources of energy have been set up and some demonstration projects are under way. Shortage of energy in China can not be expected to be overcome in a short period of time. The only way out is to adopt various kinds of energy conservation measures and increase the utilization of NRSE, while expanding the production of conventional energy. NTIS

ROLE OF POLYCRYSTALLINITY IN CdTe AND CuInSe2 PHOTOVOLTAIC CELLS
J. R. Sites (Colorado State Univ., Fort Collins.) Feb. 1994 32 p
(Contract DE-AC02-83CH-10093)
(DE94-000293; NREL/TP-451-6215) Avail: CASI HC A03/MF A01

This report describes work to conduct several investigations of thin-film polycrystalline solar cells. An analysis of high-efficiency solar cells fabricated at the University of South Florida showed significant reduction in forward recombination current, and the cells were stable over a 3-month test period. Transient voltage effects were documented in a large number of polycrystalline cells and were attributed to long-lived trapping states sensitive to voltage changes near one-half open-circuit voltage. Collection efficiency and its voltage dependence were carefully calculated. The typical effect on photocurrent at operating voltages is about 2% for CuInSe2, and less for other cells. DOE

SOLAR RESOURCE: UTILITY LOAD-MATCHING ASSESSMENT
R. Perez (State Univ. of New York, Albany.), R. Seals (State Univ. of New York, Albany.), and R. Stewart (State Univ. of New York, Albany.) Mar. 1994 48 p
(Contract DE-AC02-83CH-10093)
(DE94-000297; NREL/TP-411-6292) Avail: CASI HC A03/MF A01

This report describes work performed to estimate the load-matching capability of photovoltaics (PV) for a selected group of utilities in the continental United States. The report provides an initial quantitative estimate

of this capability for 20 utilities. This characteristic is important because it may indicate that the effective capacity, hence the value, of PV is higher than is traditionally assigned to such non-controllable, non-dispatchable resources. Load-matching capability is determined experimentally by analyzing the interaction between the load requirements of each utility and the output of locally sited PV systems. This type of investigation requires site- and time-specific insolation data that are not commonly available. Here, the needed data were inferred from geostationary satellite remote sensing of the Earth's cloud cover. A secondary objective of this study was to evaluate the suitability of this approach. The results of this investigation are presented in this report. DOE

(Contract DE-AC02-83CH-10093)

(DE94-000295; NREL/TP-411-6264) Avail: CASI HC A03/MF A01

This report describes work done under Phase 3A of the PVMaT project to address problems that are generic to the photovoltaics (PV) industry. Crystalline silicon solar cells were used in the majority of all terrestrial power modules shipped in 1992. Spire's analysis in Phase 1 of the PVMaT project indicated that the use of thin (less than or equal to 200 microns) silicon cells can substantially reduce module manufacturing costs, provided that processing yields remain as high as they are now for processing standard thickness cells. Because present solar cell tabbing and interconnecting processes have unacceptably high yield losses with such thin cells, the objective of this Phase 3A subcontract is to use Spire's light soldering technology and experience in designing and fabricating solar cell tabbing and interconnecting equipment to develop high yield throughput, fully automated processes for tabbing and interconnecting thin cells. DOE

ECONOMIC FEASIBILITY ANALYSIS OF DISTRIBUTED ELECTRIC POWER GENERATION BASED UPON THE NATURAL GAS FIRED FUEL CELL

Sep. 1993 5 p Prepared for Manes Associates, Inc., Huntington Beach, CA

(Contract DE-FC21-92MC-29227)

(DE94-005795; DOE/MC-29227/3588) Avail: CASI HC A01/MF A01

This report is an account of the work performed from May 1, 1993 to July 30, 1993 on the economic feasibility generating electrical power by natural gas-fired fuel cells. The study is comprised of a survey of energy users, the development of numeric models of an energy distribution system and a central plant utilities system that includes a fuel cell. A model of the capital cost of the hardware elements is combined with a series of ownership scenarios and an operations model that provide the necessary input for a model of the cost of ownership of a fuel cell-based power generation system. The primary model development tasks are complete. The remaining study emphasis is to perform an economic analysis of varied ownership scenarios using the model. This report outlines the progress to date. DOE

The Seventeenth DOE Solar Photochemistry Research Conference sponsored by the Division of Chemical Sciences, Office of Basic Energy Sciences, is being held June 6-10, 1993, at Cragun's Lodge and Conference Center, Brainerd, Minnesota The meeting is hosted this year by the Ames Laboratory of Iowa State University. The purpose of the meeting is to foster cooperation, collaboration, and exchange of current research ideas among grantees and contractors of the DOE Division of Chemical Sciences engaged in fundamental research on solar photochemical energy conversion. This conference provides a special opportunity for interaction among investigators from diverse traditional chemistry disciplines who share the common good of providing the knowledge and concepts needed for production of low cost fuels and chemicals or electricity by photochemical conversion of solar energy. Our special guest plenary lecturer is Professor Graham Fleming, of the University of Chicago, who will speak on ultrafast spectroscopic studies of molecular dynamics in the condensed phase. The remaining presentations on Monday will feature further investigations of ultrafast phenomena in solvation, electron transfer, and charge separation at interfaces. These will lead into the topical sessions which follow on photosynthesis, molecular models, photoinduced charge transfer in homogeneous and heterogeneous solutions, inorganic photochemistry, and photoelectrochemistry. As an added feature, the photoelectrochemistry session will include six short introductory lectures for the benefit of nonspecialists on outstanding issues and problems in that field. In this volume may be found a copy of the program, the abstracts of 28 formal presentations and 59 posters, as well as an address listing of the 114 participants. DOE

The viability of the hydride storage unit in solar hydrogen energy systems was assessed from testing results conducted in simulated solar hydrogen system environment. Hydride storage unit was shown to match technically well with the solar hydrogen energy system as a part of the hydrogen storage subsystem. Hydrogen could be stored using pressures from 5 bar to 30 bar at ambient temperature and subsequently liberated in different pressure ranges depending on the temperature of the hydride storage unit. The maximum flow rate of the hydrogen was over 10 Nl H2/min and the degree of the reversibility was better than 95%. ESA

DEVELOPMENT OF A CATALYTIC SYSTEM FOR GASIFICATION OF WET BIOMASS

D. C. Elliott, L. J. Sealock, M. R. Phelps, G. G. Neuenschwander, and T. R. Hart Aug. 1993 15 p Presented at the 1st Biomass Conference of

the Americas: Energy, Environment, Agriculture, and Industry, Burlington, VT, 30 Aug. - 2 Sep. 1993
(Contract DE-AC06-76RL-01830)
(DE94-006216; PNL-SA-22582; CONF-9308106-3) Avail: CASI HC A03/MF A01

A gasification system is under development at Pacific Northwest Laboratory that can be used with high-moisture biomass feedstocks. The system operates at 350 C and 205 atm using a liquid water phase as the processing medium. Since a pressurized system is used, the wet biomass can be fed as a slurry to the reactor without drying. Through the development of catalysts, a useful processing system has been produced. This paper includes assessment of processing test results of different catalysts. Reactor system results including batch, bench-scale continuous, and engineering-scale processing results are presented to demonstrate the applicability of this catalytic gasification system to biomass. The system has utility both for direct conversion of biomass to fuel gas or as a wastewater cleanup system for treatment of unconverted biomass from bioconversion processes. By the use of this system, high conversion of biomass to fuel gas can be achieved. Medium-Btu is the primary product. Potential exists for recovery/recycle of some of the unreacted inorganic components from the biomass in the aqueous byproduct stream. DOE

NEMO: ADVANCED ENERGY SYSTEMS AND TECHNOLOGIES
P. Lund (Helsinki Univ. of Technology, Otaniemi, Finland.) 1993 144 p In FINNISH
(DE94-721996; KTM/E-B-150) Avail: CASI HC A07/MF A02

In this report, the contents and major results of the national research program on advanced energy system and technologies (NEMO) are presented. The NEMO-program was one of the energy research programs of the Ministry of Trade and Industry during 1988-1992. Helsinki University of Technology had the responsibility of the overall coordination of the program. NEMO has been the largest resource allocation into advanced energy systems in Finland so far. The total budget was 70 million FIM. The focus of the program has been in solar energy, wind power, and energy storage. Hydrogen and fuel cells have been included in smaller amount. On all major fields of the NEMO-program, useful and high quality results have been obtained. Results of international significance include among others arctic wind energy, new approaches for the energy storage problem in solar energy applications, and the development of a completely new storage battery. International collaboration has been given high priority. The NEMO-program has also been active in informing the industries of the various business and utilization possibilities that advanced energy technologies offer. For example, major demonstration plants of each technology group have been realized. It is recommended that the further R and D should be still more focused on commercial applications. Through research efforts at universities, a good technology base should be maintained, whereas the industries should take a stronger position in commercializing new technology. Parallel to technology R and D, more public resources should be allocated for market introduction. DOE

Based upon the results of this culture screening study, Rhodospirillum rubrum is recommended for biocatalysis of the water gas shift reaction and Chlorobium thiosulfatophilum is recommended for H2S conversion to elemental sulfur. Both bacteria require tungsten light for growth and can be co-cultured together if H2S conversion is not complete (required concentration of at least 1 ppM), thereby presenting H2 uptake by Chlorobium thiosulfatophilum. COS degradation may be accomplished by utilizing various CO-utilizing bacteria or by indirectly converting COS to elemental sulfur after the COS first undergoes reaction to H2 in water. The second alternative is probably preferred due to the low expected concentration of COS relative to H2S. Mass transfer and kinetic studies were carried out for the Rhodospirillum rubrum and Chlorobium thiosulfatophilum bacterial systems. Rhodospirillum rubrum is a photosynthetic anaerobic bacterium which catalyzes the biological water gas shift reaction: CO + H2O yields CO2 + H2. Chlorobium thiosulfatophilum is also a photosynthetic anaerobic bacteria, and converts H2S and COS to elemental sulfur. DOE

(DE94-000291; NREL/TP-451-6135) Avail: CASI HC A05

This report describes work to reach two goals -- an individual goal and a wide-gap team goal. The individual goal was to investigate the 'top junction' for defects using the spectroscopic ellipsometry technique. This will include an evaluation if specific defects are associated with C, B, Sn (diffusing from the transparent conducting oxide TCO) or Na (diffusing from the glass). It may include an assessment of the function of a graded a-SiC:H buffer layer. As defects are identified and characterized, their influence on the transport properties will be assessed. This should lead to better parameters used as input to models for the electronic materials and device performance. The goal of the wide-gap team was to demonstrate, characterize, and understand improved doped and undoped 'wide gap' materials for use in achieving 15%-efficient stabilized photovoltaic modules ('wide gap' materials are defined by this team to have a band gap greater than or = 1.9 eV). The major conclusions of the research are discussed in the report. DOE

SILICON-FILM(TM) PHOTOVOLTAIC MANUFACTURING TECHNOLOGY
W. R. Bottenberg, R. B. Hall, E. L. Jackson, S. Lampo, W. P. Mulligan, and A. M. Barnett Feb. 1994 41 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000202; NREL/TP-411-5815) Avail: CASI HC A03/MF A01

This report describes work under a subcontract to upgrade AstroPower, Inc.'s facility to produce 1.22 m(exp 2) Silicon-Film(trademark) PV modules with an output of 170 Wp. The focus for the first year of the PVMaT Phase 2A project is to establish the baseline process capability and optimize the performance of the present machine. This first year's activities accelerated the advance of Silicon-Film(trademark) manufacturing technology in several ways. First, the project led directly to plans to make an early introduction of a large solar cell product. The successful fabrication of 646 cm(exp 2) wafers and solar cells paved the way for dramatically increasing the power output per solar cell. Second was the establishment of a basis for the design and construction of a 2.4 MW/yr wafer machine. Another important contribution was the determination of the importance of H(+) implantation processes for polycrystalline silicon technologies. DOE

A SOLAR ARRAY MODULE FABRICATION PROCESS FOR HALE SOLAR ELECTRIC UAVs
P. G. Carey, R. C. Aceves, N. J. Colella, J. B. Thompson, and K. A. Williams Dec. 1993 5 p
(Contract W-7405-eng-48)
(DE94-006212; UCRL-ID-115268) Avail: CASI HC A01/MF A01

We describe a fabrication process to manufacture high power to weight ratio flexible solar array modules for use on high altitude long endurance (HALE) solar electric unmanned air vehicles (UAV's). A span-loaded flying wing vehicle, known as the RAPTOR Pathfinder, is being employed as a flying test bed to expand the envelope of solar powered flight to high altitudes. It requires multiple light weight, flexible solar array modules able to endure adverse environmental conditions. At high altitudes the solar UV flux is significantly enhanced relative to sea level and extreme thermal variations occur. Our process involves first electrically interconnecting solar cells into an array followed by laminating them between top and bottom laminated layers into a solar array module. After careful evaluation of candidate polymers, fluoropolymer materials have been selected as the array laminate layers because of their inherent abilities to withstand the hostile conditions imposed by the environment. A SIMPLE MODEL FOR DETERMINING PHOTOELECTRON-GENERATED RADIATION SCALING LAWS
T. M. Dipp Dec. 1993 76 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-006130; LA-12674) Avail: Issuing Activity (Department of Energy (DOE))

The generation of radiation via photoelectrons induced off of a conducting surface was explored using a simple model to determine fundamental scaling laws. The model is one-dimensional (small-spot) and uses monoenergetic, nonrelativistic photoelectrons emitted normal to the illuminated conducting surface. Simple steady-state radiation, frequency, and maximum orbital distance equations were derived using small-spot radiation equations, a sin(exp 2) type modulation function, and simple photoelectron dynamics. The result is a system of equations for various scaling laws, which, along with model and user constraints, are simultaneously solved using techniques similar to linear programming. Typical conductors illuminated by low-power sources producing photons with energies less than 5.0 eV are readily modeled by this small-spot, steady-state analysis, which shows they generally produce low efficiency (eta(sub rsL) less than 10(exp -10.5)) pure photoelectron-induced radiation. However, the small-spot theory predicts that the total conversion efficiency for incident photon power to photoelectron-induced radiated power can go higher than 10(exp -5.5) for typical real conductors if photons having energies of 15 eV and higher are used, and should go even higher still if the small-spot limit of this theory is exceeded as well. Overall, the simple theory equations, model constraint equations, and solution techniques presented provide a foundation for understanding, predicting, and optimizing the generated radiation, and the simple theory equations provide scaling laws to compare with computational and laboratory experimental data. Advances in recent years of high strength/lightweight materials, high performance magnetic bearings, and power electronics technology has spurred a renewed interest by the transportation, utility, and manufacturing industries in flywheel energy storage (FES) technologies. FES offers several advantages over conventional electrochemical energy storage, such as high specific energy and specific power, fast charging time, long service life, high turnaround efficiency (energy out/energy in), and no hazardous/toxic materials or chemicals are involved. Potential applications of FES units include power supplies for hybrid and electric vehicles, electric vehicle charging stations, space systems, and pulsed power devices. Also, FES units can be used for utility load leveling, uninterruptable power supplies to protect electronic equipment and electrical machinery, and for intermittent wind or photovoltaic energy sources. The purpose of this workshop is to provide a forum to highlight technologies that offer a high potential to increase the performance of FES systems and to discuss potential solutions to overcome present FES application barriers. This document consists of viewgraphs from 27 presentations. DOE

BIOMASS POWER INDUSTRY: ASSESSMENT OF KEY PLAYERS AND APPROACHES FOR DOE AND INDUSTRY INTERACTION
Jan. 1994 35 p
(Contract DE-AC02-83CH-10093)
(DE94-000238; DOE/CH-10093/257) Avail: CASI HC A03/MF A01

A review team established by the Department of Energy conducted an assessment of the U.S. biomass power industry. The review team visited with more than 50 organizations representing all sectors of the biomass power industry including utilities, independent power producers, component manufacturers, engineering and construction contractors, agricultural organizations, industrial users, and regulatory organizations. DOE solicited industry input for the development of the Biomass Power Division's Five Year Plan. DOE believed there was a critical need to obtain industry's insight and working knowledge to develop the near- and long-term plans of the program. At the heart of this objective was the desire to identify near-term initiatives that the program could pursue to help accelerate the further development of biomass power projects. DOE

POLYMER ELECTROLYTE FUEL CELLS
S. Gottesfeld 1994 11 p Presented at the 11th International Seminar on Primary and Secondary Battery Technology and Application, Deerfield Beach, FL, 28 Feb. - 3 Mar. 1994
(Contract W-7405-eng-36)
(DE94-007558; LA-UR-94-659; CONF-940210-1) Avail: CASI HC A03/MF A01

The recent increase in attention to polymer electrolyte fuel cells (PEFC's) is the result of significant technical advances in this technology and the

initiation of some projects for the demonstration of complete PEFC-based power system in a bus or in a passenger car. A PEFC powered vehicle has the potential for zero emission, high energy conversion efficiency and extended range compared to present day battery powered EV's. This paper describes recent achievements in R&D on PEFC's. The major thrust areas have been: (1) demonstration of membrane/electrode assemblies with stable high performance in life tests lasting 4000 hours, employing ultra-low Pt loadings corresponding to only 1/2 oz of Pt for the complete power source of a passenger car; (2) effective remedies for the high sensitivity of the Pt electrocatalyst to impurities in the fuel feed stream; and (3) comprehensive evaluation of the physicochemical properties of membrane and electrodes in the PEFC, clarifying the water management issues and enabling effective codes and diagnostics for this fuel cell. DEVELOPMENT OF A COMPUTER MODEL FOR POLYCRYSTALLINE THIN-FILM CuInSe2 AND CdTe SOLAR CELLS
J. L. Gray, R. J. Schwartz, and Y. J. Lee Mar. 1994 62 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-006853; NREL/TP-451-6398) Avail: CASI HC A04/MF A01

Solar cells operate by converting the radiation power from sun light into electrical power through photon absorption by semiconductor materials. The elemental and compound material systems widely used in photovoltaic applications can be produced in a variety of crystalline and non-crystalline forms. Although the crystalline group of materials have exhibited high conversion efficiencies, their production cost are substantially high. Several candidates in the poly- and micro-crystalline family of materials have recently gained much attention due to their potential for low cost manufacturability, stability, reliability and good performance. Among those materials, CuInSe2 and CdTe are considered to be the best choices for production of thin film solar cells because of the good optical properties and almost ideal band gap energies. Considerable progress was made with respect to cell performance and low cost manufacturing processes. Recently conversion efficiencies of 14.1 and 14.6% have been reported for CuInSe2 and CdTe based solar cells respectively. Even though the efficiencies of these cells continue to improve, they are not fully understood materials and there lies an uncertainty in their electrical properties and possible attainable performances. The best way to understand the details of current transport mechanisms and recombinations is to model the solar cells numerically. By numerical modeling, the processes which limit the cell performance can be sought and therefore, the most desirable designs for solar cells utilizing these materials as absorbers can be predicted. The problems with numerically modeling CuInSe2 and CdTe solar cells are that reported values of the pertinent material parameters vary over a wide range, and some quantities such as carrier concentration are not explicitly controlled. LARGE-AREA, TRIPLE-JUNCTION a-Si ALLOY PRODUCTION SCALE-UP
R. Oswald, J. ODowd, and W. Ashenfelter Mar. 1994 18 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-006856; NREL/TP-411-6397) Avail: CASI HC A03/MF A01

This report describes work to improve the efficiency of large-area, multi-junction amorphous silicon (a-Si) alloy modules. Equipment capable of producing modules up to 0.74 m(exp 2) in area is on line and process development has begun. Preliminary cost analysis/reduction has begun to ensure that these development efforts will result in a commercialization of the large-area technology. The approach was to transfer the high-efficiency multi-junction technology from R&D into the manufacturing environment by using three different substrate sizes. Initial attempts to transfer the multijunction silicon process were made using a 0.1 m(exp 2) substrate (approximately 1 ft(exp 2)). These efforts resulted in a module with a measured aperture area efficiency of 10.32%. Simultaneous with the transfer of the silicon technology, the most complicated aspect of the technology transfer, Solarex began process development techniques on large-area modules by using the 0.37 m(exp 2) substrates. These efforts resulted in modules with a total area efficiency of 7%. Finally, initial runs on substrates 0.74 m(exp 2) were made to debug the large-area equipment in preparation of transferring the knowledge gained in the processing of the smaller substrates. DOE

This document provides a summary of the design of the 2MW carbonate fuel cell power plant which will be built and tested under DOE cooperative agreement DE-FC2l-92MC29237. The report is divided into sections which describe the process and stack module design, and appendices which provide additional design detail. Section 2.0 provides an overview of the program, including the project objectives, site location, and schedule. A description of the overall process is presented in Section 3.0. The design of the fuel cell stack modules is described in section 5.0, which discusses the design of the fuel cell stacks, multi-stack enclosures, and stack modules. Additional detail is provided in a report appendix, the Final Design Criteria Summary. This is an abstract of the design criteria used in the design of the submodules and modules. DOE

FIELD OPERATION TEST OF UTILITY INTERACTIVE LOAD CONDITIONER WITH PHOTOVOLTAIC CELLS AT A DEMONSTRATION HOUSE
K. Ishihara, Y. Mita, T. Iwahori, and J. Iga May 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-757271; CRIE-T-92090) Avail: CASI HC A03

This paper reports the result of a field operation test of a utility load conditioner in a demonstration house equipped with photovoltaic cells. The photovoltaic cells have an area of 42 m(exp 2) and a capacity of 8.6 kW at 250 V. The utility load conditioner is of single-phase, three-wire type, with a power converting capacity of 5 kW/6 kVA. The storage battery consists of two banks of sealed lead-acid batteries, each bank comprising 18 cells of 12 V - 65 Ah in series. As a result of the testing, the load conditioner was verified to cause only the excess power generated by the photovoltaic cells during daytime to flow into the storage battery banks under a reverse current flow operation mode. When the photovoltaic cell output is below power demand, the load conditioner draws as much power as is short from the storage battery banks. Under a storage battery absorbing operation mode, the conditioner makes the storage battery absorb the excess power while suppressing the reverse flow. Autonomous operation during a power failure, transfer to the storage battery absorbing operation mode, and return to the reverse current flow operation mode at power failure restoration have all operated smoothly without overcharging the storage batteries. A high energy storage efficiency of 70% in a pumped storage power plant has been achieved in a week-long operation. DOE

OPTIMAL PLANNING OF RESIDENTIAL PHOTOVOLTAIC SYSTEMS UNDER VARIOUS RATE STRUCTURE
E. Imamura and H. Asano May 1993 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-757272; CRIE-Y-93001) Avail: CASI HC A03

With respect to residential electric power utilization and supply systems utilizing photovoltaic power generation, the installation inducible economic conditions were searched using a linear programming technique, and influences by charge systems were evaluated and discussed. A photovoltaic system model consists of a photovoltaic panel, a control panel incorporated inverter, and a storage battery set. For the amount of power generated by the photovoltaic system, mean values for total insolation in Tokyo each for winter, summer, and intermediate seasons were used, assuming the photovoltaic system efficiency at 10% and the battery charge/discharge efficiency at 70%. Residential power load patterns were hypothesized from 200 to 1000 kWh/month depending on the demand scale. As a result of the analysis, it was made clear that the condition the photovoltaic system is accepted by residential housing is such that the price for the photovoltaic system including the inverter becoming 1/5 of the present price, and the price for the battery including the charge/discharge control device becoming 1/3 make the cost break-even. In the case of time-band based charge system, it is shown that the case where the ratio of daytime charge to

nighttime charge is three makes the coordination of the battery and the photovoltaic system optimal. DOE

OPERATIONAL EXPERIENCE AND EVALUATION OF A DUAL-ELEMENT STRETCHED-MEMBRANE HELIOSTAT
J. W. Strachan and Geest VanDer, J. Jan. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-94AL-85000)
(DE94-008827; SAND-93-2453) Avail: CASI HC A03

A dual-element, stretched-membrane central receiver heliostat was designed and manufactured in 1989 by a private US company engaged in the development of commercial central receiver solar technology. The two-module collector, with a collection area of 97.5 sq m, extends stretched-membrane mirror technology on several fronts with face-down stow capability and a digital controller that integrates tracking and focusing control on a single programmable control board. The solar collector was installed at Sandia's National Solar Thermal Test Facility in Albuquerque, NM, and it was evaluated over a three-and-a-half year period which ended in Sep. 1993. The measured performance and the operational and maintenance characteristics of this commercial prototype are the subject of this report. The results of beam quality measurements, tracking repeatability tests, measurements of beam movement in elevated winds, performance tests of the focusing system, and all-day beam quality and tracking tests are presented, and the authors offer a detailed discussion of the knowledge gained through operation and maintenance and of the improvements made or suggested to the heliostat's design. NATO CONTRIBUTIONS TO EUROPEAN ENVIRONMENTAL SECURITY Final Report
Kent H. Butts 30 Dec. 1993 61 p
(AD-A275918) Avail: CASI HC A04/MF A01

Environmental issues are promoting instability and conflict at an ever increasing rate. Forward-thinking international security strategists suggest that these catalytic issues be addressed before they lead to costly conflict. The U.S. Department of Defense has committed itself to using DOD assets to address these environmental problems. This study builds upon these visionary concepts to recommend that NATO develop an environmental assistance program to address issues that threaten stability in regions strategically important to European security. With NATO searching for a new mission to demonstrate its relevance in the post-cold war era, such a program has great potential benefit in helping to mitigate significant environment problems. It would also allow NATO to promote military-to-military contacts and enhance communication with former adversaries. DTIC

IN-BED MULTIPORT SAMPLING SYSTEM Final Report, Nov. 1991 - May 1993
L. C. Buettner, J. J. Mahle, and D. K. Friday Dec. 1993 17 p
(DA Proj. 101-62622-A-553)
(AD-A275908; ERDEC-TR-134) Avail: CASI HC A03/MF A01

Knowledge of the transient behavior in fixed-bed separation processes is required to design advanced air purification systems. Measuring transient behavior experimentally can be difficult because of rapid changes in pressure and temperature in the bed. An apparatus has been developed which simultaneously isolates multiple vapor phase concentration samples at selected axial positions within the bed for subsequent analysis. Results are presented for the calibration operation of this sampling apparatus using a laboratory pressure swing adsorption system. DTIC

INVESTIGATION OF CARBON DIOXIDE IN THE CENTRAL SOUTH PACIFIC OCEAN (WOCE SECTIONS P-16C AND P-17C) DURING THE TUNES/2 EXPEDITION OF THE R/V THOMAS WASHINGTON, JULY-AUGUST, 1991
T. Takahashi, J. G. Goddard, S. Rubin, D. W. Chipman, and S. C. Sutherland Dec. 1993 163 p
(Contract DE-FG02-90ER-60983)
(DE94-006638; DOE/ER-60983/3) Avail: CASI HC A08/MF A02

This report summarizes the results of carbon dioxide and associated hydrographic measurements made during the oceanographic expedition, TUNES/2, aboard the R/V Thomas Washington in the central South Pacific Ocean. During the 40 day expedition, the total carbon dioxide concentration in 1000 seawater samples were determined using a coulometer system and the pCO2 in 940 seawater samples were determined using an equilibrator/gas chromatograph system. The alkalinity values in 900 water samples were computed using these measurements. In addition, 156 coulometric measurements were made for the Certified Reference Solutions (Batch No. 6) and yielded a mean value of 2303.2 +/- 1.5 (mu)mol/kg. The chemical characteristics for the major water masses have been determined. DOE

INFORMATION RESOURCES FOR US DEPARTMENT OF ENERGY POLLUTION PREVENTION PROGRAMS
K. L. Peterson, L. J. Snowden-Swan, and R. S. Butner Jan. 1994 62 p

(Contract DE-AC06-76RL-01830)
(DE94-006677; PNL-9002) Avail: CASI HC A04/MF A01

In support of the U.S. Department of Energy's (DOE's) pollution prevention efforts being conducted under the aegis of DOE's Office of Environmental Restoration and Waste Management (EM) program, Pacific Northwest Laboratory was tasked with evaluating pollution prevention information resources. The goal of this activity was to improve the effectiveness of DOE's pollution prevention activities through improved information flow, both within the complex and, more specifically, between DOE and other organizations that share similar pollution prevention challenges. This report presents findings with respect to the role of information collection and dissemination within the complex, opportunities for teaming from successes of the private sector, and specific information needs of the DOE pollution prevention community. These findings were derived from a series of interviews with pollution prevention coordinators from across the DOE complex, review of DOE site and facility pollution prevention plans, and workshops with DOE information users as well as an information resources workshop that brought together information specialists from private industry, nonprofit organizations, as well as state and regional pollution prevention assistance programs. THE GLOBAL CLIMATOLOGY NETWORK PRECIPITATION DATA
T. C. Peterson (National Climatic Data Center, Asheville, NC.), D. R. Easterling (National Climatic Data Center, Asheville, NC.), R. S. Vose, and J. K. Eischeid 1993 7 p Presented at the Symposium on Precipitation and Evaporation, Bratislava, Czechoslovakia, 20-24 Sep. 1993
(Contracts DE-AC05-84OR-21400; DE-AI05-90OR-21956; DE-AI05-90ER-60952)
(DE93-019199; CONF-9309223-1) Avail: CASI HC A02/MF A01

Several years ago, in response to growing concern about global climate change, the US National Climatic Data Center and the Carbon Dioxide Information Analysis Center undertook an effort to create a baseline global land surface climate data set called the Global Historical Climatology Network (GHCN, Vose et al., 1992). GHCN was created by merging several large existing climate data sets into one data base. Fifteen separate data sets went into the creation of the GHCN version 1.0. GHCN version 1.0 was released in 1992. It has 7,533 precipitation stations, but the number of stations varies with time. A slight majority (55%) have records in excess of 50 years, and a significant proportion (13%) have records in excess of 100 years. The longest period of record for any given station is 291 years (1697-1987 for Kew, United Kingdom). DOE

TREATMENT OF CLOUD RADIATIVE EFFECTS IN GENERAL CIRCULATION MODELS
W. C. Wang 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract DE-FG02-90ER-61073)
(DE94-001864; DOE/ER-61073/3) Avail: Issuing Activity (Department of Energy (DOE))

This is a renewal proposal for an on-going project of the Department of Energy (DOE)/Atmospheric Radiation Measurement (ARM) Program. The objective of the ARM Program is to improve the treatment of radiation-cloud in GCMs so that reliable predictions of the timing and magnitude of greenhouse gas-induced global warming and regional responses can be made. The ARM Program supports two research areas: (1) The modeling and analysis of data related to the parameterization of clouds and radiation in general circulation models (GCMs); and (2) the development of advanced instrumentation for both mapping the three-dimensional structure of the atmosphere and high accuracy/precision radiometric observations. The present project conducts research in area (1) and focuses on GCM treatment of cloud life cycle, optical properties, and vertical overlapping. The project has two tasks: (1) Development and Refinement of GCM Radiation-Cloud Treatment Using ARM Data; and (2) Validation of GCM Radiation-Cloud Treatment. DOE

TIME-DEPENDENT BEHAVIOR OF MOUNT PINATUBO AEROSOL
J. Michalsky and N. Larson 1993 5 p Presented at the Optical Society of America Meeting on Optical Remote Sensing of the Atmosphere, Salt Lake City, UT, 8-12 Mar. 1993
(Contracts DE-FG02-90ER-61072; DE-AC06-76RL-01830)
(DE94-001877; DOE/ER-61072/6; CONF-930346-4) Avail: CASI HC A01/MF A01

The 15-16 June 1991 eruption of Mount Pinatubo delivered approximately 20 million metric tons of SO2 to the stratosphere. The SO2 plume from Mount Pinatubo straddled the equator resulting in a more symmetrical global distribution of the H2SO4-H2O aerosol that results from the photochemical conversion of the SO2. This paper follows the aerosol optical depth change over three-northern mid-latitude sites for the first sixteen months following the eruption. The technique to derive volcanic aerosol optical depth from ground-based measurements (which are, by their nature, total column aerosol optical depth measurements) follows the technique developed in an earlier paper to examine El Chichon aerosol. The three sites' time-dependent behavior is discussed and compared. Comparison of El Chichon and Mount Pinatubo aerosol optical depth change with time is also discussed for the one site that operated before, through, and after both eruptions. DOE

CONCENTRATION SYSTEM PERFORMANCE DEGRADATION IN THE AFTERMATH OF MOUNT PINATUBO
J. J. Michalsky, R. Perez, R. Seals, and P. Ineichen 1993 7 p Presented at the SOLAR 1993: American Society of Mechanical Engineers (ASME)/American Solar Energy Society (ASES) Joint Solar Energy Conference, Washington, DC, 25-28 Apr. 1993
(Contracts DE-FG02-90ER-61072; DE-AC04-76DP-00789; NSF INT-90-02363)
(DE94-001879; DOE/ER-61072/8; CONF-930435-10) Avail: CASI HC A02/MF A01

Major volcanic eruptions occur every few years, but most have little effect on solar radiation or climate. However, in the last ten years two volcanoes have decreased solar radiation and influenced weather at a level that might be expected at the frequency of about once a century. The Mexican volcano El Chichon and the Philippine volcano Mount Pinatubo put 6 and 20 million metric tons of SO2 in the stratosphere, respectively. SO2 is converted into H2SO4, which mixes with water to produce aerosol. Since there is no weather in the stratosphere and the aerosol is small, these aerosol particles remain suspended until coagulation and sedimentation bring them to the troposphere where they are removed by normal wet and dry deposition processes. The extinction in the direct solar irradiance from El Chichon was found to peak during the winter of 1983 at about 11% for northern, mid latitudes. Mount Pinatubo's peak extinction during 1992 was about 15%. Data from four northern, mid-latitude sites are examined to compare the direct consequences of the volcano's eruption on the performance of concentrating solar energy systems and the indirect effects that may be associated with Mount Pinatubo's perturbation of the weather. THE CONTRIBUTION OF AERONAUTICS AND ASTRONAUTICS TO THE QUALITY OF LIFE ON EARTH [UEBER DEN BEITRAG DER LUFT- UND RAUMFAHRT ZUR LEBENSQUALITAET AUF DER ERDE]
Heinz-Hermann Koelle and Michael Mielke 1 Aug. 1993 70 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ILR-Mitt-283(1993); ETN-94-95745) Avail: CASI HC A04

A century of aviation and four decades of space flight and their respective developments in the 20th century are considered. The contributions of aeronautics and astronautics with respect to improving the quality of life on Earth are projected for the 21st century by analyzing the potential of the respective technologies to the individual elements comprising a formal goal system defining the 'quality of life'. The individual fields of specific activities as well as individual projects, are evaluated with respect to their potential contributions during the next hundred years. The results obtained are compared with the potential contributions of maritime and surface transportation systems which are considered to form the transportation sector of society. Eight other sectors of society are evaluated in the same manner to allow a comparison of their contributions with the transportation

sector in general, and the contributions of the fields of aeronautics and astronautics in particular. ESA

EMISSIONS OF GREENHOUSE GASES FROM THE USE OF TRANSPORTATION FUELS AND ELECTRICITY
M. A. DeLuchi Nov. 1993 523 p
(Contract W-31-109-eng-38)
(DE94-006166; ANL/ESD/TM-22-Vol-2) Avail: CASI HC A22/MF A04

This volume contains the appendices to the report on Emission of Greenhouse Gases from the Use of Transportation Fuels and Electricity. Emissions of methane, nitrous oxide, carbon monoxide, and other greenhouse gases are discussed. Sources of emission including vehicles, natural gas operations, oil production, coal mines, and power plants are covered. The various energy industries are examined in terms of greenhouse gas production and emissions. Those industries include electricity generation, transport of goods via trains, trucks, ships and pipelines, coal, natural gas and natural gas liquids, petroleum, nuclear energy, and biofuels. DOE

CONTROL AND MONITORING OF HEAVY METAL EMISSIONS [RASKASMETALLIPAEAESTOEJEN VALVONTA JA TARKKAILU]
Leena Aunela and Kari Larjava Sep. 1993 50 p In FINNISH Sponsored by the Ministry of Environment
(ISSN 1235-0605)
(VTT-TIED-1508; ISBN-9-51-384442-0; ETN-94-96040) Copyright Avail: CASI HC A03/MF A01

The control and monitoring of heavy metal emissions has not become an established practice in Finland. Control and monitoring regulations are issued to plants on a discretionary case by case basis. In Germany the air protection law as well as its subordinated decrees and technical instructions define the principles governing the control and monitoring of heavy metals released into the atmosphere within individual industries. The German practice and its applicability as a model for Finland are examined. The methods used to measure heavy metal concentrations are currently selected by the measurers themselves and the suitability of these methods is not subject to official control. Determining heavy metal concentrations in the flue gases of thermic processes is a demanding task since many different contributing factors are associated with its implementation. It is typical for heavy metals that they occur simultaneously in the vaporous and particulate phases. A sample of both phases must be taken simultaneously in order to determine the total concentration. The situation in Finland with regard to the collection of particulate heavy metals is quite good, because of the established particle measurement practice. Integrating the particle collection line into the vapor phase collection line makes it more difficult to satisfy the requirements of particle sampling (isokinetic sampling, the use of several measuring points). The processing and analysis of particulate samples must be further developed in order to obtain accurate and comparable results. ESA

STRATEGIES FOR SURVIVAL IN THE NEW ENVIRONMENTAL ERA Report, Aug. 1992 - Apr. 1993
Louisa H. McAllister Apr. 1993 37 p
(AD-A276827; NDU/ICAF-93-RS1) Avail: CASI HC A03/MF A01

Preservation of the environment has become an issue of primary importance worldwide; hence, American industry can expect a future in which public and private sector insistence on environmentally safe products--already high--will rise steadily and increasingly determine economic viability. This report focuses on the causes and effects of air pollution and the requirements of the Clean Air Act Amendments of 1990. To survive in today's environmentally sensitive atmosphere, companies must recognize and accept that the environment has become deeply entrenched as one of the central concerns of the American consumer. Moreover, to be successful, companies must be willing to make substantial organizational and operational changes. Several strategies for survival are suggested. Although the task will not be easy, the companies that succeed will find themselves among the most respected and profitable in the world. DTIC

CARBON CYCLE MODELING CALCULATIONS FOR THE IPCC
D. J. Wuebbles and A. K. Jain 12 Aug. 1993 19 p Presented at the International Panel on Climate Change Meeting, Carqueiranne, France, 18 Sep. 1993
(Contract W-7405-eng-48)
(DE94-004332; UCRL-JC-115337; CONF-9309300-1) Avail: CASI HC A03/MF A01

We carried out essentially all the carbon cycle modeling calculations that were required by the IPCC Working Group 1. Specifically, IPCC required two types of calculations, namely, 'inverse calculations' (input was CO2 concentrations and the output was CO2 emissions), and the 'forward calculations' (input was CO2 emissions and output was CO2 concentrations). In particular, we have derived carbon dioxide concentrations and/or emissions for several scenarios using our coupled climate-carbon cycle modelling system. DOE

CARBON DIOXIDE ABATEMENT AS A DIFFERENTIAL GAME
O. Tahvonen 1993 31 p
(DE94-722023; OY/TTO-DP-4) Avail: CASI HC A03/MF A01

The report combines predictions on greenhouse warming, CO2 abatement costs and adaptation costs in a differential game framework. The specified model makes it possible to solve the payoffs of the subgame perfect solution of a two state variable nonautonomous problem with N unequal countries. Abatement cost parameters are calibrated with a global energy sector model and climate parameters are based on empirical time series. Simulation suggests that the backstop technology assumption in the abatement cost model may imply drastic cuts in optimal emission levels. Compared to the Nash noncooperative equilibrium a pareto optimal agreement is found to be beneficial for developing countries but more costly for the industrial world. Given the present damage estimates, the losses due to an emission stabilizing agreement may be 400 times higher than maximum potential gains from cooperation. DOE

GREENHOUSE GAS EMISSION IMPACTS OF ELECTRIC VEHICLES UNDER VARYING DRIVING CYCLES IN VARIOUS COUNTRIES AND US CITIES
Michael Q. Wang and William W. Marr 10 Feb. 1994 23 p Presented at the 5th Global Warming Science and Policy International Conference and Expo, San Francisco, CA, 4-7 Apr. 1994
(Contract W-31-109-eng-38)
(DE94-007647; ANL/ES/CP-82079; CONF-940422-1) Avail: CASI HC A03/MF A01

Electric vehicles (EV's) can reduce greenhouse gas emissions, relative to emissions from gasoline-fueled vehicles. However, those studies have not considered all aspects that determine greenhouse gas emissions from both gasoline vehicles (GV's) and EV's. Aspects often overlooked include variations in vehicle trip characteristics, inclusion of all greenhouse gases, and vehicle total fuel cycle. In this paper, we estimate greenhouse gas emission reductions for EV's, including these important aspects. We select four US cities (Boston, Chicago, Los Angeles, and Washington, D.C.) and six countries (Australia, France, Japan, Norway, the United Kingdom, and the United States) and analyze greenhouse emission impacts of EV's in each city or country. We also select six driving cycles developed around the world (i.e., the US federal urban driving cycle, the Economic Community of Europe cycle 15, the Japanese 10-mode cycle, the Los Angeles 92 cycle, the New York City cycle, and the Sydney cycle). Note that we have

not analyzed EV's in high-speed driving (e.g., highway driving), where the results would be less favorable to EV's; here, EV's are regarded as urban vehicles only. We choose one specific driving cycle for a given city or country and estimate the energy consumption of four-passenger compact electric and gasoline cars in the given city or country. Finally, we estimate total fuel cycle greenhouse gas emissions of both GV's and EV's by accounting for emissions from primary energy recovery, transportation, and processing; energy product transportation; and powerplant and vehicle operations. DOE

HOMOGENEOUS GLOBAL MEAN TEMPERATURE TIME SERIES
T. C. Peterson (National Climatic Data Center, Asheville, NC.), D. R. Easterling (National Climatic Data Center, Asheville, NC.), R. S. Vose, and J. K. Eischeid 1993 3 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract DE-AC05-84OR-21400)
(DE94-002194; CONF-940115-10) Avail: CASI HC A01/MF A01

A multi-agency effort has been underway to create a homogeneous global baseline data set suitable for studying climate change. The joint release of the Global Historical Climatology Network (GHCN) version 1 in 1992 by the National Climatic Data Center/NOAA and the Carbon Dioxide Information Analysis Center/DOE gave the climate research community the largest monthly land surface global climate data set available to date with over 6,000 temperature stations, 39% of which have more than 50 years of data, and 10% have more than 100 years of data. Fifteen different global or regional data sets were merged to create GHCN version 1. Ten of these source data sets have temperature data, but only two have been tested and adjusted for inhomogeneities in the station time series. The majority of the station temperature time series in GHCN have not been systematically examined for discontinuities. DOE

FINE RESOLUTION ATMOSPHERIC SULFATE MODEL DRIVEN BY OPERATIONAL METEOROLOGICAL DATA: COMPARISON WITH OBSERVATIONS
C. M. Benkovitz, S. E. Schwartz, C. M. Berkowitz, and R. C. Easter Sep. 1993 10 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contracts DE-AC02-76CH-00016; DE-AC06-76RL-01830)
(DE94-002994; BNL-49536; CONF-940115-11) Avail: CASI HC A02/MF A01

The hypothesis that anthropogenic sulfur aerosol influences clear-sky and cloud albedo and can thus influence climate has been advanced by several investigators; current global-average climate forcing is estimated to be of comparable magnitude, but opposite sign, to longwave forcing by anthropogenic greenhouse gases. The high space and time variability of sulfate concentrations and column aerosol burdens were established by observational data; however, geographic and time coverage provided by data from surface monitoring networks is very limited. Consistent regional and global estimates of sulfate aerosol loading, and the contributions to this loading from different sources can be obtained only by modeling studies. Here we describe a sub-hemispheric to global-scale Eulerian transport and transformation model for atmospheric sulfate and its precursors, driven by operational meteorological data, and we reportthe results of calculations for Oct. 1986 for the North Atlantic and adjacent continental regions. The model, which is based on the Global Chemistry Model, uses meteorological data from the 6-hour forecast model of the European Center for Medium-Range Weather Forecast to calculate transport and transformation of sulfur emissions. Time- and location-dependent dry deposition velocities were estimated using the methodology of Wesely and colleagues. Chemical reactions include gaseous oxidation of SO2 and DMS by OH, and aqueous oxidation of SO2 by H2O2 and O3. Anthropogenic emissions were from the NAPAP and EMEP 1985 inventories and biogenic emissions based on Bates et al. Calculated sulfate concentrations and column burdens exhibit high variability on spatial scale of hundreds of km and temporal scale of days. Calculated daily average sulfate concentrations closely reproduce observed concentrations at locations widespread over the model domain. DOE

FORMATION OF GAS-PHASE PEROXIDES IN A RURAL ATMOSPHERE: AN INTERPRETATION OF THE RECENT SOS/SERON FIELD RESULTS
J. H. Lee, I. N. Tang, and J. B. Weinstein-Lloyd Sep. 1993 7 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contracts DE-AC02-76CH-00016; DE-FG02-91ER-61206)
(DE94-002995; BNL-49600; CONF-940115-12) Avail: CASI HC A02/MF A01

Hydrogen perioxide (H2O2) and certain organic peroxides such as hydroxymethyl-hydroperoxide (HMHP), are gas-phase oxidants present in the atmosphere at ppbv concentration levels. These oxidants play an important role in atmospheric chemistry. In addition, precipitation containing H2O2 is toxic to trees, and it has also been suggested that organic peroxides formed presumably by ozone reactions with biogenic alkenes are responsible for leaf disorders. Recently, we have developed a nonenzymatic method or aqueous-phase H2O2 measurement, using Fenton reagent and fluorescent hydroxy-benzoic acid. The new method, in conjunction with the well-known method of p-hydroxyphenylacetic acid and horseradish peroxidase for total peroxides, and together with an improved gas scrubber to mitigate sampling line problems, has been successfully deployed in recent SOS/SERON field measurements in rural Georgia. For the first time, continuously measured and speciated gas-phase peroxide data have become available, making it possible to examine some aspects of the ozone chemistry leading to the formation of these oxidants. It is observed that daily H2O2 maximum frequently occurs at a different time than does HMHP and that H2O2 concentration, but not HMHP, tends to correlate with solar fluxes measured at the same location. These findings seem to indicate that the formation mechanisms for H2O2 and organic peroxides are basically different. It is likely that H2O2 is formed from radical-radical recombination, while HMHP is formed by ozone-alkene reactions. Since the gas-phase ozone-alkene reactions are usually too slow to account for the diurnal concentration variations observed for HMHP, heterogeneous processes involving ozone and alkenes are also a possibility. DOE

PROCEEDINGS OF THE NINTH ANNUAL PACIFIC CLIMATE (PACLIM) WORKSHOP
K. T. Redmond, ed. and V. L. Tharp, ed. Mar. 1993 21 p Workshop held in Asilomar, CA, 21-24 Apr. 1992
(Contract DE-FC03-90ER-61010)
(DE94-003024; CONF-9204273-Summ) Avail: CASI HC A03/MF A01

We describe the climatology of the western United States as seen from two 1-month perspectives, Jan. and Jul. 1988, of the National Meteorological Center large-scale global analysis, the Colorado State University Regional Atmospheric Modeling System (RAMS), and various station observation sets. An advantage of the NMC analysis and the RAMS is that they provide a continuous field interpolation of the meteorological variables. It is more difficult to describe spatial meteorological fields from the available sparse station networks. We assess accuracy of the NMC analysis and RAMS by finding differences between the analysts, the model, and station values at the stations. From these comparisons, we find that RAMS has much more well-developed mesoscale circulation, especially in the surface wind field. However, RAMS climatological and transient fields do not appear to be substantially closer than the large-scale analysis to the station observations. The RAMS model does provide many other meteorological variables, such as precipitation, which are not readily available from the archives of the global analysis. Thus, RAMS could, at the least, be a tool to augment the NMC large-scale analyses. DOE

REMOVAL OF CO2 FROM FLUE GASES BY ALGAE
C. Akin (Institute of Gas Technology, Chicago, IL.), A. Maka (Institute of Gas Technology, Chicago, IL.), S. Patel (Institute of Gas Technology, Chicago, IL.), J. Conrad (Institute of Gas Technology, Chicago, IL.), and J. Benemann 1993 33 p
(Contract DE-FC22-92PC-92521)
(DE94-008039; DOE/PC-92521/T97) Avail: CASI HC A03/MF A01

The objective of this research program is to determine the feasibility of the alga Botryococcus braunii as a biocatalyst for the photosynthetic conversion of flue gas CO2 to hydrocarbons. Free and immobilized cells

of Botryococcus braunii were grown in aqueous medium supplemented with nitrogen, phosphorus, and mineral nutrients. Air and CO2 enriched air (10% to 15% (v/v) CO2) in the gas phase and 0.2% to 2% NaHCO3 in the liquid medium served as the carbon source. Growth and hydrocarbon formation characteristics of free and immobilized cultures of Botryococcus braunii were determined in bench-scale photobioreactors. Technical and economic feasibility of the conversion of flue gas CO2 to hydrocarbons by Botryococcus braunii culture systems was evaluated. In free cell systems, the hexane extractable oil productivity was about 15 to 37 grams of oil per 100 grams of cell dry weight. In immobilized cell systems, the oil production ranged between 5% and 47% at different immobilization systems and immobilized surface locations, with an average of 19% of cell biomass dry weight. The feasibility and economic evaluation estimated the cost of oil produced from flue gas CO2 by algae to range between $45 and $75 per barrel assuming that a hydrocarbon yield of about 50% of the biomass weight is achievable and a credit of $60 per ton of carbon removed is available. A future research program leading to development of a multistage process, consisting of closed systems for heavy inoculum buildup followed by lower cost open systems for oil production is recommended. (Contract DE-FG02-89ER-69017)
(DE94-003629; DOE/ER-69017/5) Avail: CASI HC A02/MF A01

Research in 1992-93, the second year of the project, involved, inter alia, the following topics: continuation of studies of proxy climatic records to try to extend the record of large-scale climatic conditions back into previous centuries and to determine if there are reliable regional analogs for larger scale climatic fluctuations; examination of indices of long-term climatic variability to determine if climate has become more, or less, variable over time. This involves studies of both instrumental and proxy data sets for sites throughout the world; Continuation of studies of mid-winter polar boundary layer climate as a possible indicator of greenhouse gas-induced climate changes; documentation of the linkages between observed temperature and precipitation changes on regional space scales and changes in large-scale atmospheric circulation patterns; regridding of global temperature anomalies using an equidistant grid, optimal interpolation scheme, and stratification of data by extent of urbanization at each station, then recomputation of regional and hemispheric temperature trends. Significant progress was made in all of these areas. In the report, we summarize results of the work accomplished. DOE

PHYSICAL BASIS FOR CLIMATE CHANGE MODELS
R. Goody and M. Gerstell 18 Oct. 1993 3 p
(Contract DE-FC03-90ER-61010)
(DE94-003827; DOE/ER-61010/T22) Avail: CASI HC A01/MF A01

The objectives for this research were two-fold: to identify means of using measurements of the outgoing radiation stream from earth to identify mechanisms of climate change; and to develop a flexible radiation code based upon the correlated-k method to enable rapid and accurate calculations of the outgoing radiation. The intended products are three papers and a radiation code. The three papers are to be on Entropy fluxes and the dissipation of the climate system, Radiation fingerprints of climate change, and A rapid correlated-k code. DOE

AN EVALUATION OF RAMS RADIATION SCHEMES BY FIELD MEASUREMENTS
S. Zhong and J. C. Doran Feb. 1994 5 p Presented at the RAMS Workshop, Ft. Collins, CO, 15-17 Feb. 1994
(Contract DE-AC06-76RL-01830)
(DE94-008053; PNL-SA-23581; CONF-940265-1) Avail: CASI HC A01/MF A01

At present, two radiation schemes are used in RAMS: the Mahrer and Pielke (M-P) scheme and the Chen and Cotton (C-C) scheme. The M-P scheme requires little computational expense, but does not include the radiative effects of liquid water or ice; the C-C scheme accounts for the radiative effects of liquid water and ice but is fairly expensive computationally. For simulations with clouds, the C-C scheme is obviously a better choice, but for clear sky conditions, RAMS users face a decision regarding which radiation scheme to use. It has been noted that the choice of radiation scheme may result in significantly different results for the same case. To examine the differences in the radiative fluxes and the boundary layer structure corresponding to the two radiation schemes in RAMS we have carried out a study where RAMS was used to simulate the same case with two different radiation schemes. The modeled radiative fluxes by the two schemes were then compared with the field measurements. A description of the observations and the case study, a comparison and discussion of the results, and a summary and conclusions follow. DOE

IDENTIFICATION OF RESEARCH RELATING TO THE CRITICAL LOADS CONCEPT AND ITS POTENTIAL APPLICATION TO THE REGULATION OF ACIDIC DEPOSITION
N. Bhatti Dec. 1993 31 p
(Contract W-31-109-eng-38)
(DE94-008234; ANL/DIS/TM-4) Avail: CASI HC A03/MF A01

The overwhelming majority of strategies currently implemented to regulate acidic deposition have focused on source-based or emission-control techniques. In the past few years, however, the fact that such source-based strategies may not be sufficient to prevent adverse ecological effects and may therefore need to be supplemented with other control options, such as receptor-based strategies, has become apparent. Partly in response to this insufficiency of regulatory controls, the U.S. Congress has required the National Acid Precipitation Assessment Program to determine what deposition levels are needed to prevent such ecological damage, whether such safe deposition levels (i.e., critical loads) can realistically be identified, and what the costs and benefits of attaining such deposition levels are. This report reviews and culls the existing research on these alternative control strategies, emphasizing the critical loads concept, to determine the advantages and limitations and the cost-benefit relationships associated with receptor-based control options. The results of this study indicate that in spite of the significant limitations associated with the critical loads concept, this strategy dominates all discussions of nonsource-based control options and offers considerable advantages, including cost effectiveness, over the more traditional source-based control methods. Summaries of 10 of the most relevant studies dealing with alternative control strategies and the costs and benefits associated with them are also presented in this report. DOE

ENVIRONMENTAL ISSUES RELATED TO BIOMASS: AN OVERVIEW
M. Hughes (Department of Agriculture, Washington, DC.) and J. W. Ranney 1993 11 p Presented at the 1st Biomass Conference of the Americas: Energy, Environment, Agriculture, and Industry, Burlington, VT, 30 Aug. - 2 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-007226; CONF-9308106-4) Avail: CASI HC A03/MF A01

Now that public attention has grown increasingly focused on environmentalism and climate change, the commercial use of biomass could greatly accelerate. Renewable feedstocks like biomass can provide better environmentally balanced sources of energy and other nonfood products than fossil fuels. The future of biomass is uncertain, however, because public attention focuses on both its potential and its challenges. This paper is divided into five sections. Section 2 briefly addresses economic environmental issues. The extent to which externalities are accounted for in the market price of fuels plays a significant role in determining both the ultimate size of biofuel markets and the extent of the environmental benefits of feedstock cultivation and conversion processes. Sections 3 and 4 catalog the main hazards and benefits that are likely to arise in the large-scale commercialization of biomass fuel and note where the major uncertainties lay. Environmental issues arise with the cultivation of each feedstock and with each step in the process of its conversion to fuel. Feedstocks are discussed in Section 3 in terms of three main groups: wastes, energy crops, and traditional agricultural crops. In Section 4, conversion processes are also divided into three groups, on the basis of the end energy carrier: gas, liquid, and solid and electricity. Section 5 provides a conclusion and summary. CLIMATE EFFECTS OF ANTHROPOGENIC SULFATE: SIMULATIONS FROM A COUPLED CHEMISTRY/CLIMATE MODEL

C. C. Chuang, J. E. Penner, K. E. Taylor, and J. J. Walton Sep. 1993 7 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-7405-eng-48)
(DE94-004352; UCRL-JC-114078; CONF-940115-15) Avail: CASI HC A02/MF A01

In this paper, we use a more comprehensive approach by coupling a climate model with a 3-D global chemistry model to investigate the forcing by anthropogenic aerosol sulfate. The chemistry model treats the global-scale transport, transformation, and removal of SO2, DMS, and H2SO4 species in the atmosphere. The mass concentration of anthropogenic sulfate from fossil fuel combustion and biomass burning is calculated in the chemistry model and provided to the climate model where it affects the shortwave radiation. We also investigate the effect, with cloud nucleation parameterized in terms of local aerosol number, sulfate mass concentration, and updraft velocity. Our simulations indicate that anthropogenic sulfate may result in important increases in reflected solar radiation, which would mask locally the radiative forcing from increased greenhouse gases. Uncertainties in these results will be discussed. DOE

FOOD SECURITY IN THE CONTEXT OF GLOBAL ENVIRONMENTAL CHANGE
N. J. Rosenberg Nov. 1993 18 p Presented at the Agriculture in the Context of Global Change Conference, Cincinnati, OH, 7-11 Nov. 1993
(Contract DE-AC06-76RL-01830)
(DE94-007481; PNL-SA-23709; CONF-9311191-1) Avail: CASI HC A03/MF A01

United Nations predictions and other sources indicate that world population could grow to 8.5 billion by 2025 (Keyfitz 1989) and 11 billion by the end of the coming century (UNFPA 1990). As new information becomes available on the effectiveness of population control programs, the rise of virulent diseases and other factors, these numbers change -- sometimes smaller, sometimes larger still. Whatever the numbers actually turn out to be, global agricultural production will have to increase several-fold from present levels to feed and clothe the growing population and to improve worldwide standards of nutrition. The capacity of global agriculture to ensure food security through increased and sustained agricultural production depends on our ability to manage, conserve and in some cases increase the resource base available to the industry of agriculture. The resources that underpin agriculture are land, water and genetic diversity. The first two of these are the subject of this paper. Genetic diversity is the subject of another paper in this volume. MEXICO CITY OZONE CONCENTRATIONS AS A FUNCTION OF READILY-AVAILABLE METEOROLOGICAL PARAMETERS
M. J. Brown 1994 20 p Presented at the Institute of Mexican Petroleum (IMP) Conference, Mexico City, Mexico, Feb. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-007576; LA-UR-94-572; CONF-940266-1) Avail: CASI HC A03

Daily maximum ozone concentrations measured at four sites within the Mexico City basin during the winter months are plotted as functions of different meteorological parameters that are routinely measured at surface stations. We found that ozone concentrations are most strongly correlated to the increase in daytime temperature and the maximum daytime wind speed. We also discovered that high ozone values at the sites in the southern end of the basin occur when winds come out of the northeast. In contrast, wind direction was found to be uncorrelated with high ozone values at the northern sites. From straightforward combinations of the meteorological variables, we derived some simple rules for estimating lower and upper bounds on the ozone concentration. Scatter in the data was too long to give significance to best-fit equations and statistics. Additionally, a small rawinsonde data set was used to investigate ozone's dependence on boundary-layer height and near-surface temperature gradient. Results were inconclusive, however, due to the small size of the data set. DOE

QUANTIFIED ESTIMATES OF TOTAL GWPs FOR GREENHOUSE GASES TAKING INTO ACCOUNT TROPOSPHERIC CHEMISTRY
D. J. Wuebbles, J. S. Tamaresis, and K. O. Patten Nov. 1993 130 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-007846; UCRL-ID-115850) Avail: CASI HC A07

The purpose of this report is to give an interim account of the progress being made at Lawrence Livermore National Laboratory (LLNL) in developing an improved capability for assessing the direct and indirect effects on Global Warming Potentials. Much of our current efforts are being devoted to improving the capability for modeling of global tropospheric processes in our state-of-the-art zonally-averaged chemical radiative-transport model of the troposphere and stratosphere. These efforts are in preparation for an improved evaluation and better quantification of the indirect GWP's resulting from effects on tropospheric ozone from ethane and other gases with significant human-related emissions. There are three major findings that should result from this project that should have significant impacts on EPA and its programs. First, the current and ongoing studies of the direct and indirect GWP's should have a significant influence on the continuing national and international assessments of climate change. Second, the improved capability for modeling of chemical and physical processes should lead to enhanced understanding of the controlling factors influencing ozone, hydroxyl and other key tropospheric constituents. Third, the enhanced modeling capability should be important to future studies of human-related influences on tropospheric and stratospheric chemical processes. DOE

STATISTICAL INTERCOMPARISON OF GLOBAL CLIMATE MODELS: A COMMON PRINCIPAL COMPONENT APPROACH
S. K. Sengupta and J. S. Boyle Nov. 1993 43 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-008671; UCRL-ID-116155; PCMDI-13) Avail: CASI HC A03

Variables describing atmospheric circulation and other climate parameters derived from various GCM's and obtained from observations can be represented on a spatio-temporal grid (lattice) structure. The primary objective of this paper is to explore existing as well as new statistical methods to analyze such data structures for the purpose of model diagnostics and intercomparison from a statistical perspective. Among the several statistical methods considered here, a new method based on common principal components appears most promising for the purpose of intercomparison of spatio-temporal data structures arising in the task of model/model and model/data intercomparison. A strategy for such an intercomparison is outlined in two steps: First, the commonality of spatial structures in two (or more) fields is captured in the common principal vectors, and second, the corresponding principal components obtained as time series are then compared on the basis of similarities in their temporal evolution. DOE

DRY DEPOSITION OF PAN TO GRASSLAND VEGETATION
P. V. Doskey, M. L. Wesely, D. R. Cook, and W. Gao 1994 6 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-31-109-eng-38)
(DE94-005111; ANL/ER/CP-80342; CONF-940115-17) Avail: CASI HC A02/MF A01

Peroxyacetyl nitrate or PAN (CH3C(O)OONO2) is formed in the lower troposphere via photochemical reactions involving nitrogen oxides (NO(x)) and non-methane hydrocarbons (NMHC's). PAN has a lifetime in the free troposphere of about three months and is removed by photolysis or reaction with OH. Dry deposition will decrease its lifetime, although the few measurements that were made indicate that this process is slow. Measurements of the uptake of PAN by alfalfa in growth chambers indicated that the dry deposition velocity (downward flux divided by concentration at a specified height) was 0.75 cm/s. Garland and Penkett measured a dry deposition velocity of 0.25 cm/s for PAN to grass and soil in a return-flow wind tunnel. Shepson et al. analyzed trends of PAN and O3 concentrations in the stable nocturnal boundary layer over mixed, deciduous/coniferous forests at night, when leaf stomata were closed, and concluded that the deposition velocity for PAN was at least 0.5 cm/s. We measured the dry deposition velocity of PAN to a grassland site in the midwestern United States with a modified Bowen ratio technique. Experiments were conducted on selected days during Sep., Oct., and Nov. of 1990. An energy balance Bowen ratio station was used to observe the differences in air temperature and water vapor content between heights of 3.0 and 0.92 m and to evaluate the surface energy balance. Air samples collected at the same two heights in Teflon (reg sign) bags were analyzed for PAN by a gas chromatographic technique. We present an example of the variations of PAN concentrations and gradients observed during the day and compare measurements of the dry deposition velocity to expectations based on the physicochemical properties of PAN. CURRENT POLICIES OF THE MAJOR COUNTRIES COPING WITH THE GLOBAL WARMING PROBLEM AND-THE ENERGY DEMAND AND SUPPLY
10 Nov. 1993 193 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-757291; IEE-SR-248) Avail: CASI HC A09

Investigation and analysis were made of attitude maintained by the US, EC, Germany and France to cope with the global warming and energy problems after the conclusion of the Framework Convention on Climate Change. Intending to take large scale and long term measures, the US framed the Energy Policy Act, ratified the Convention and announced the Action Program. For the environmental protection, the EC maintains a positive attitude however with rather weak measures taken. All EC's program to decrease CO2 emissions aims at the compensation of decrease in East Germany for the increase in South Europe. However, if the carbon energy tax can not be introduced, it is difficult to achieve the aim. Germany has the most drastic aim established to decrease CO2 emissions by 25 to 30%. Even after achieving the aim, Germany will be equal to the present EC in CO2 emissions per person. Therefore, German people are judged to be not considerably sacrificial. Having positively introduced the nuclear power since the oil crisis, France is a developed country where CO2 emissions are very small per person, aiming at stabilization of the emissions. DOE

EFFECTS OF LONG-TERM ELEVATED ATMOSPHERIC CO2 CONCENTRATIONS ON PINUS PONDEROSA
K. A. Surano, ed. and J. R. Kercher, ed. Oct. 1993 140 p
(Contract W-7405-eng-48)
(DE94-008832; UCRL-ID-115638) Avail: CASI HC A07/MF A02

This report details the results from an experiment of the effects of long-term elevated atmospheric CO2 concentrations on ponderosa pine (Pinus ponderosa) saplings and seedlings. The study began in 1983 as a pilot study designed to explore the feasibility of using open-top chambers for continuous multi-year exposures on sapling-sized trees and to examine possible CO2 responses so that future research could be adequately designed. However, following the first year of exposure, preliminary results from the study indicated that measurements of CO2 responses should be intensified. Open-top chambers proved suitable for use in multiyear exposures of mature trees. With respect to the preliminary examination of CO2 responses, many interesting observations were made. The nature of the preliminary results suggests that future long-term field CO2 exposures on perennial species may be critical to the understanding and preparation for future environments. Other research reported here attempted to adapt an existing western coniferous forest growth and succession model for use in elevated CO2 scenarios using differential species responses, and assessed the usefulness of the model in that regard. Seven papers were processed separately for inclusion in the appropriate data bases. DOE

FOCUSED FEASIBILITY STUDY FINAL FIELD SAMPLING PLAN
Oct. 1993 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277445) Avail: CASI HC A04

At the direction of APG-DSHE, the project has been separated into three work phases to allow for data evaluation and risk determination before a full focused feasibility study is conducted. Phase 1 of the project consists of an aerial photography investigation, surface/marine geophysical surveys, a flowmeter logging program, sampling surface and subsurface soils, an ecological risk assessment of the Beach Point Test Site, and analysis of chemical groundwater data generated through the separate Canal Creek Groundwater Monitoring Program. Tasks described for Phase 2 of the FFS will be performed upon evaluation of data needs identified subsequent to completion of the Phase 1 tasks. Phase 2 investigations include installation of additional groundwater monitoring wells, sampling of the new and previously existing monitoring wells, a flowmeter logging program, downhole geophysical logging of new monitoring wells (and one previously existing well), and possible soil gas surveys. Phase 3 tasks may be performed after phase 1, and at any point thereafter, if it is determined that contamination found in the Beach Point Test Site warrants treatment. DTIC

TRANSPORT AND DIFFUSION IN TURBULENT FIELDS MODELING AND MEASUREMENTS TECHNIQUES
Hadassah Kaplan, Nathan Dinar, Avi Lacser, and Yehudah Alexander
1993 458 p The 35th Oholo Conference held in Eilat, Israel, 28 Oct. - Nov. 1, 1991 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278114) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This volume contains the invited and contributed lectures that were presented at the 35th Oholo Conference, held in Eilat, Israel, during 28 Oct. - 1 Nov. 1991. This meeting, in common with the 28th Oholo Conference (1984) in Zichron Yaakov, was organized by the Environmental Sciences Division of the Israel Institute for Biological Research. The present conference dealt with theoretical, experimental, and practical aspects of 'Transport and Diffusion in Turbulent Fields'. The scientists attending the meeting came from over a dozen different countries and met to exchange ideas and share results of research in the following broad range of topics: (1) Basic studies and novel methods in modeling atmospheric processes--theory and experiments involving eddy flow; turbulent mixing, transport, and diffusion in various media, ranging from microscale to macroscale; (2) Analysis of concentration fluctuations--theoretical developments; observations in different atmospheric conditions; (3) Experimental techniques and methods of data acquisition--use of various sensors; laboratory experiments and observations in the atmosphere and in the ocean; and (4) Interactions and feedback between theoretical models and experimental results. COUNTING PARTICLES EMITTED BY STRATOSPHERIC AIRCRAFT AND MEASURING SIZE OF PARTICLES EMITTED BY STRATOSPHERIC AIRCRAFT Final Technical Report, 1 May 1990 - 31 Dec. 1992
James Charles Wilson 19 Apr. 1994 28 p
(Contract NCC2-666)
(NASA-CR-195908; NAS 1.26:195908) Avail: CASI HC A03/MF A01

The ER-2 condensation nuclei counter (CNC) has been modified to reduce the diffusive losses of particles within the instrument. These changes have been successful in improving the counting efficiency of small particles at low pressures. Two techniques for measuring the size distributions of particles with diameters less than 0.17 micrometers have been evaluated. Both of these methods, the differential mobility analyzer (DMA) and the diffusion battery, have fundamental problems that limit their usefulness for stratospheric applications. We cannot recommend either for this application. Newly developed, alternative methods for measuring small particles include inertial separation with a low-loss critical orifice and thin-plate impactor

device. This technique is now used to collect particles in the multisample aerosol collector housed in the ER-2 CNC-2, and shows some promise for particle size measurements when coupled with a CNC as a counting device. The modified focused-cavity aerosol spectrometer (FCAS) can determine the size distribution of particles with ambient diameters as small as about 0.07 micrometers. Data from this instrument indicates the presence of a nuclei mode when CNC-2 indicates high concentrations of particles, but cannot resolve important parameters of the distribution. MAGNETOHYDRODYNAMICS OF THE EARTH'S CORE. 1: STEADY, ROTATING MAGNETOCONVECTION. 2: MAGNETIC ROSSBY WAVES Ph.D. Thesis
Michael I. Bergman 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

We review the evidence for core-mantle thermal coupling, which includes spatial correlation between the static magnetic field features, lateral thermal anomalies in the lower mantle, core-mantle boundary topography, and possibly virtual geomagnetic pole (VGP) path during magnetic dipole reversals. Maps of the main magnetic field at the Earth's surface suggest that anomalous electrical currents may be present in the equatorial zone, with a large azimuthal wavenumber m = 1 contribution. We invert the surface magnetic field for the magnitude of ideal magnetic dipoles distributed in various ways throughout the outer core. We find a better, smoother fit with equatorial dipoles than with polar dipoles. The equatorial anomalies in the surface main field correlate with regions of high surface magnetic secular variation, further suggesting persistent motions in the core. Although the convective equations are highly non-linear due to the high Rayleigh number of the Earth's core, so that time-dependent motions are certainly present, we are interested here in the possibility of steady motions that result from either free convection or forced convection and that might cause static features in the magnetic field. We provide destabilization in our model by uniformly fluxing buoyancy across the bottom boundary with a concominant buoyancy sink at the top boundary. The Rayleigh number Ra is a measure of the destabilization. We first apply our method to a non-rotating, electrically insulating spherical fluid shell in order to demonstrate the method's viability. We then look for solutions in a rapidly rotating spherical fluid shell (high Taylor number Ta). We next return to the rotating spherical shell, impose a poloidal magnetic field, and look for the magnetic analog of the polar models. When the Lorentz force is comparable to the Coriolis force (Elsasser number El = O(1)), the modes fill the shell and most efficiently transport buoyancy. Finally, we study axisymmetric flows forced by a high buoyancy flux across the upper boundary near the equator and a low flux near the poles. A second topic that we study in this thesis involves a possible consequence of compositional convection in the Earth's core: the formation of a stably stratified layer at the top of the outer core. ODIN AERONOMY SCIENCE: A PHASE-A REPORT BY THE AERONOMY SCIENCE WORKING GROUP FOR THE ODIN SATELLITE
D. P. Murtagh, G. Witt, R. Mewe, H. vanderWoerd, N. Kaempfer, P. Taalas, J. Askne, and A. Winnberg 21 Sep. 1993 32 p
(ISSN 0280-4441)
(AP-31; ETN-94-95881) Avail: CASI HC A03/MF A01

The phase A study of a satellite with the joint goals of studying the Earth's atmosphere and the interstellar medium using sub-mm techniques is reported. The satellite was given the name Odin. The main instrument is a four channel sub-mm receiver with bands at 425, 480, 551, and 515 GHz. The bands are tunable to at best +/- 1 and are served by two channel spectrometers with selectable resolutions of 0.1 and 1 MHz. In addition, an optical spectrometer covering the wavelength region 200 to 800 nm with a channel at 1.27 micrometers is included to obtain complementary measurements by the Differential Optical Absorption Spectroscopy (DOAS) technique. (NR Proj. R03-GE-81)
(AD-A276447; NCCOSC/RDT/E-TD-2609) Avail: CASI HC A03/MF A01

This document reports efforts on two main goals: to study the short-term ionospheric variability and to study the effects of this variability on high frequency (HF) skywave field strength. To achieve the first goal, ionospheric soundings are being done at 5-minute intervals at San Diego, CA, and at Logan, UT. This time interval was chosen to adequately resolve variations produced by locally generated gravity waves. To study the effects of short-term ionospheric variability on high frequency communications, a circuit is being established to measure the variability of the received HF signal strength. The chosen circuit will have the transmitter located in Forsyth, MT, and the receiver in Imperial Beach, CA (approximately 20 miles south of NRaD). DTIC

ANALYSIS OF IONOSPHERIC PARAMETERS IN EUROPE AND CREATION OF THE PREDICTION ALGORITHM Final Report

E. E. Tsedilina and A. Eviatar Feb. 1993 121 p

(Contract DAJA45-92-C-0006)

(AD-A276342) Avail: CASI HC A06/MF A02

Investigation of the correlation and gradient characteristics of the basic parameters of the ionospheric profile (foF2 and H'F) and Maximum usable frequency (MUF(3000)F2) were estimated with the aim of the creation of ionospheric model for HF radio predictions and communications. Ionospheric data on European sounding stations (Digisondes) spaced at the distances of 1000 to 1100 km from each other were used for the period in one year from September 1990 to October 1991. Various diurnal and seasonal dependencies for all characteristics considered were obtained. DTIC

MICROWAVE DIELECTRIC BEHAVIOR OF SOILS. REPORT 1: SUMMARY OF RELATED RESEARCH AND APPLICATIONS

John O. Curtis Dec. 1993 119 p

(AD-A275980; WES/TR/EL-93-25-Rept-1) Avail: CASI HC A06/MF A02

As a precursor to developing a well-documented database of complex electrical properties of soils as a function of signal frequency, sample moisture, sample temperature, and soil type, a comprehensive study of existing data collection methodology and analytical modeling was undertaken. Of particular utility are chronological tables of experimental and analytical milestones as well as an extensive reference list. Several appendices are included that are helpful in understanding soil/electromagnetic wave interactions and new concepts in modeling soil structure. DTIC

N94-31353# Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.

MICROWAVE DIELECTRIC BEHAVIOR OF SOILS. REPORT 2: A UNIQUE COAXIAL MEASUREMENT APPARATUS

John O. Curtis Dec. 1993 49 p

(AD-A275982; WES/TR/EL-93-25-Rept-2) Avail: CASI HC A03/MF A01

A reflection/transmission laboratory apparatus and data collection methodology are described that can be used to measure the complex dielectric response of moist soils over the 100 MHz to 18 GHz frequency range. The experimental setup includes a square cross-sectional coaxial sample holder, a vector network analyzer system for signal generation and detection, and an external bath for sample temperature control. Data collected on liquids whose dielectric response is well known verify that the electrical property calculation algorithm functions properly. DTIC

PROCEEDINGS OF THE 4TH TUNNEL DETECTION SYMPOSIUM ON SUBSURFACE EXPLORATION TECHNOLOGY

R. M. Miller and R. F. Dennis 29 Apr. 1993 693 p Symposium held in Golden, CO, 26-29 Apr. 1993

(Contract DAAK70-92-C-0015)

(AD-A276372) Avail: CASI HC A99/MF A06

These Proceedings document the 47 technical papers delivered during the Fourth Tunnel Detection Symposium on Subsurface Exploration Technology held 26-29 April 1993 in Golden, Colorado. The objective of the Symposium was the exchange of technical information on the most recent advances in subsurface exploration technology. Previous series of symposia on this subject (1981, 1984 and 1988) were focused on the application of detecting and locating deep tunnels (to 300 meters) in hard rock geological environments. The scope of this symposium was expanded to include a wider variety of subsurface applications, viz., shallow tunnels (to 30 meters), natural cavities, historical, archaeological and other underground structures, buried utilities, environmental clean-up, etc. Subjects discussed included field methods and experimentation, instrumentation, methods for analysis of field data and interpretation, field problems, application of theories of subsurface exploration, mathematical and scale modeling, and related subjects. MICROWAVE DIELECTRIC BEHAVIOR OF SOILS. REPORT 3: MEASUREMENT AND MODELING

John O. Curtis Dec. 1993 91 p

(AD-A276060; WES/TR/EL-93-25-Rept-3) Avail: CASI HC A05/MF A01

Making use of a coaxial reflection/transmission experimental procedure described in Report 2 of this series, a large number of complex dielectric property measurements were made of soil samples that ranged in texture from a poorly graded sand to a pure nonswelling clay mineral. Two methods of modeling the results are discussed. One is an equivalent circuit representation that accounts for both low-frequency conductivity and higher frequency dielectric relaxation losses in the soil/water mixture. The other model consists of a fractal description of soil structure combined with the concept of long-range electrical connectivity at less than 100 percent saturation. DTIC

ANALYSIS OF DEEP SEISMIC REFLECTION AND OTHER DATA FROM THE SOUTHERN WASHINGTON CASCADES

W. D. Stanley and S. Y. Johnson 1993 8 p Presented at the Fuels Technology Contractors' Review Meeting, Morgantown, WV, 16-18 Nov. 1993

(Contract DE-AT21-92MC-29267)

(DE94-005958; DOE/MC-29267/94/C0314; CONF-931156-16) Avail: CASI HC A02/MF A01

Limited possibilities exist for new hydrocarbon exploration regimes in the Pacific Northwest. Extensive geophysical studies have been used to outline a proposed sedimentary basin hidden beneath volcanic rocks of the Cascades region of southwestern Washington (Stanley et. al, 1992, AAPG Bull. 76, 1569-1585). Electrical geophysical imaging using the magnetotelluric (MT) method first detected thick, electrically conductive sequences believed to represent late Cretaceous to Oligocene marine sedimentary rocks. The conductive section occurs at depths from about 1 km to 10 km in the area west of a line between Mt. Rainier and Mt. Adams, extending westward to a line between Mt. St. Helens and just west of Morton, WA. The conductive rocks reaches thicknesses as great as 10 km. The anomalous rocks appear to be very near the surface in the axis of anticanes that bring Eocene marine shales to shallow depths. Careful consideration of physical properties and the correspondence of the morphology of the units to known fold sets suggests that the high conductivities are related to lithologic/stratigraphic units rather than to variations in physical properties. Our preference for the lithology of the anomalous section, based upon a study of regional geology and structure, is one dominated by marine shales of Eocene and older age. Other possible lithologies that have been evaluated for the conductive section include nonmarine sedimentary units of Tertiary age, highly altered volcanic flows, and pre-Tertiary metasedimentary rocks with large percentages of graphite. We refer to this anomalously conductive region as the southern Washington Cascades conductor (SWCC). DOE

CLOUD STUDIES SEEN FROM A PHYSICAL CHEMIST'S PERSPECTIVE

S. E. Schwartz Nov. 1993 10 p Presented at the 6th European Symposium on Physico-Chemical Behaviour of Atmospheric Pollutants, Varese, Italy, 18-22 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC02-76CH-00016)

(DE94-006059; BNL-49744; CONF-9310268-1) Avail: CASI HC A02

Substantial advances have been made in recent years in describing the rates of chemical reactions in clouds. Inputs to these calculations are concentrations of reagent species, solubilities of reactive gases, rate expressions for interphase mass transport, rate expressions for

aqueous-phase reaction of the dissolved species, the liquid-water content of the cloud and its drop-size spectrum, and the composition of the cloudwater (especially pH) as it affects solubility and reaction rates. Armed with this information one can calculate the rates of reactions of interest. The question still remains as to the accuracy of such calculations. To answer this one needs field measurements, of cloud properties and the concentrations of reagents -- to permit evaluation of reaction rates -- and of differences in composition that may be attributed to chemical reaction. However, determination of rates and extents of in-cloud reactions presents a major challenge because of uncertainties associated with measurements of concentration changes. Even attribution of a measured composition change to a specific reaction is difficult. Another challenge to the field measurement community is determining the size dependence of cloudwater composition (especially pH) and the resultant difference between reaction rates based on bulk composition and actual reaction rates integrated over the cloud droplet spectrum. This paper reviews these issues and offers suggestions for field measurements to confirm model based-understanding of these processes. DOE

LIGHTNING-INDUCED COUPLING OF THE RADIATION BELTS TO GEOMAGNETICALLY CONJUGATE IONOSPHERIC REGIONS Ph.D. Thesis
William Cargill Burgess 1993 168 p
Avail: Univ. Microfilms Order No. DA9317753

Very low frequency (VLF) radio observations in Antarctica and North America provide the first evidence that bursts of energetic electrons from the earth's radiation belts commonly precipitate into geomagnetically conjugate ionospheric regions in response to lightning. The electrons, with energies ranging from tens of keV to over one MeV, appear to be scattered out of their otherwise stable trap in the earth's magnetic field by magnetospheric interactions with a regularly observed class of transient, lightning-generated VLF radio waves known as ducted whistlers. The precipitating electrons ionize atmospheric molecules at altitudes between 40 and 90 km, creating transient enhancements of ionization levels in conjugate locations. These ionospheric disturbances can be detected by their characteristic perturbations, sometimes called 'Trimpi events,' of the amplitude and phase of VLF transmitter signals propagating subionospherically within 200 to 250 km of the disturbed areas. The first detailed, one-to-one comparison of such signal perturbations, monitored in conjugate regions, with the multipath structure, arrival azimuths, and predicted electron scattering of simultaneously observed ducted whistlers suggests that every ducted whistler precipitates bursts of radiation belt electrons. If so, the estimated rate at which ducted whistlers contribute to radiation belt losses is comparable to that predicted for plasmaspheric hiss, a different class of magnetospheric wave that is often considered to control the structure of the belts. Lightning could therefore play a significant role in the maintenance of radiation belt equilibrium. Dissert. Abstr.

THE BASEMENT FRACTURE PATTERN OF SOUTHERN ONTARIO: A TECTONIC INTERPRETATION BASED ON LANDSAT TM IMAGERY, AIRPHOTOS AND FIELD DATA M.S. Thesis
Andrea Loy Rutty 1993 190 p
(ISBN-0-315-87086-9; CTN-94-61248) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The fracture pattern in the area overlying the Proterozoic central metasedimentary belt boundary zone (CMBBZ) and its north northeast trending extension below the flat-lying Paleozoic strata and Quaternary cover between Lake Ontario and Kashagawigamog Lake, southern Ontario, has been determined using Landsat satellite imagery, aerial photographs, and field studies. Image processing routines and photogeologic methods for delineating regional bedrock fracture patterns in highly glaciated and cultivated terrains are presented. Three principal sets of lineament orientations are found throughout the study area. These fractures are parallel to joints and faults within the Paleozoic strata, interpreted to be pre-Cenozoic in age. The approximately 023 deg trend parallels the underlying CMBBZ and may be related to its reactivation during late Cretaceous extension. Pop-up structures in the Balsam Lake area nucleated on joints parallel to the 106-108 deg lineament set and appear to be post-glacial in age.

TRANSPORT PHENOMENA IN THE EARTH'S PLASMA SHEET Ph.D. Thesis
Vassilis Angelopoulos 1993 196 p
Avail: Univ. Microfilms Order No. DA9317905

We present a series of studies that utilize observation and modeling in order to characterize transport in the earth's plasma sheet out to distances of 23 R(sub E). After a brief description of the dissertation's goals in Chapter 1, we analyze in Chapter 2 representative cases of high speed flows in the inner central plasma sheet along with the concurrent behavior of the plasma and magnetic field. We argue that such flows are organized in 10 min. time scale entities of convection enhancements that we term bursty bulk flow (BBF) events. BBF's have a substructure that is on a 1 min time scale, referred to as 'flow bursts'. BBF's represent intervals of enhanced, predominantly earthward transport of mass energy and magnetic flux. In Chapter 3, we use an algorithm to automatically detect BBF's and study their statistical properties. BBF's cause the plasma sheet to be in a more dipolarized, higher temperature state for a long time after their subsidence. Despite their short duration, BBF's can account for most of the measured earthward transport of particles, energy, and magnetic flux in the plasma sheet. The concept of BBF's as a particular state of transport in the plasma sheet is applied in Chapter 4 to the study of the non-BBF, quiet state of the inner plasma sheet. We construct the average ion velocity pattern in the quiet inner plasma sheet. We show that a semi-empirical magnetic field model of the magnetotail along with the inferred cross tail electric field and the measured average density reproduce the observed velocity averages assuming that the flow is the sum of corrotation, an E x B flow, and a model-derived diamagnetic drift Despite the qualitative agreement of the average flow pattern with our model calculations, the flow exhibits variability much larger than its average. The non-BBF flow is highly irregular and fundamentally unsteady, a reason why convection in the quiet state of the plasma sheet may be able to avoid a pressure balance inconsistency with the lobes. Chapter 5 explores whether a segregation of plasma sheet states similar to the one applied to the inner plasma sheet can also be extended to the outer plasma sheet.

Hourly vertical incidence ionograms have been obtained with the digisonde and copy of the ARTIST output in 5 1/4 inch floppy disks sent to Forth Monmouth regularly. The digisonde has been working with a good performance for this period. The refrigerating system of the shielding room of the digisonde has been improved to keep the temperature at the convenient level. A new set of receiving antennas is under construction. They will provide a better receiving signal and a better discrimination between ordinary and extraordinary rays. DTIC

RADAR SCATTERING FROM THE SUMMER POLAR MESOSPHERE: THEORY AND OBSERVATIONS Ph.D. Thesis
John Yungdo Nagamich Cho 1993 220 p
Avail: Univ. Microfilms Order No. DA9319373

The anomalously large radar reflectivities observed in the summer

polar mesosphere have eluded satisfactory explanation until now. We propose that the following chain of causality is responsible for the so-called polar mesosphere summer echoes (PMSE): The uniquely low temperatures in the summer mesopause produce ice aerosols. Because the aerosols exist in a plasma, they become electrically charged. The ambient electrons become coupled to the aerosols through electric fields and their effective diffusivity is retarded due to the large size of the aerosols. The reduction in diffusivity allows electron density inhomogeneities to be maintained at the radar Bragg scales. The radar waves are then scattered by the inhomogeneities. We support the above concept by developing a quantitative theory of ambipolar diffusion in the mesosphere. We then apply the results to isotropic turbulence and Fresnel radar scatter to show that the observed radar reflectivities can be explained by the theory. We show that the presence of realistic charged aerosols are sufficient to explain PMSE. We also show that dressed aerosol radar scatter, proposed by others as a generation mechanism for PMSE, can only apply to echoes detected by UHF radars. We present data taken with the Sondrestrom 1.29-GHz radar and attribute it to dressed aerosol scatter. In the summer of 1991, we used the Cornell University portable radar interferometer (CUPRI) to observe the mesosphere while rockets carrying in situ sensors were flown through two PMSE occurrences and a noctilucent cloud/PMSE event. We present a selection of first results from this campaign (NLC-91). The first simultaneous height comparison between noctilucent clouds and PMSE show that the radar scattering region was near or slightly above the visible cloud layer. We also infer from aspect sensitivity measurements and Doppler spectrograms that there were two distinct types of PMSE: enhanced turbulent scatter and partial (Fresnel) reflection from steep edges in the electron density. Both mechanisms require an anomalously low electron diffusion coefficient. Dissert. Abstr.

ATMOSPHERIC STRUCTURE SIMULATION: AN AUTOREGRESSIVE MODEL FOR SMOOTH GEOPHYSICAL POWER SPECTRA WITH KNOWN AUTOCORRELATION FUNCTION Interim Report, 1 Oct. 1991 - 20 Jan. 1993
James H. Brown 5 Feb. 1993 59 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276691; AD-E201762; PL-TR-93-2185; ERP-1128) Avail: CASI HC A04

Within a defined domain, geophysical phenomena often are characterized by smooth continuous power spectral densities having a negative power law slope. Frequently, Fourier transform analysis has been employed to generate synthetic scenes from pseudorandom arrays by passing the stochastic data through a Fourier filter having a desired correlation structure and power spectral dependency. This report examines the possibility of producing synthetic structure by invoking autoregression analysis as contrasted with the Fourier method. Since computations that apply multidimensional fast Fourier transforms to large data arrays consume enormous resources and time, the goal of this study is to seek an alternative method to reduce the computational burden. Future editions of the Phillips Laboratory Strategic High Altitude Atmospheric Radiance Code (SHARC) will feature an ability to calculate structured radiance. The methods explored herein provide a process that can complement or in some cases supplement methods presently being used. DTIC

A REASSESSMENT OF THE IN-SITU DIELECTRIC CONSTANT OF POLAR FIRN
Austin Kovacs, Anthony J. Gow, and Rexford M. Morey Dec. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A276999; CRREL-93-26) Avail: CASI HC A03

The success in using VHF and UHF frequency systems for sounding polar ice sheets has been tempered by an uncertainty in the in-situ dielectric constant epsilon' which controls the effective velocity V(sub e) of an electromagnetic wave propagating in an air-ice mixture. An empirical equation for determining epsilon' versus density (specific gravity, rho) was proposed in 1968 by Robin et al. where epsilon' = (1 + 0.851 rho)(exp 2). However, this expression has met with uncertainty because wide-angle radar refraction sounding techniques have produced values of epsilon' that are lower than Robin's equation predicts. This report discusses radar soundings made on the McMurdo Ice Shelf, Antarctica, and compares the resulting epsilon' values with Robin's equation, laboratory measurements on firn and ice, and other expressions given in the literature for determining epsilon' versus the specific gravity of dry firn and ice. Our findings indicate that the form of Robin's equation is valid. However, our analysis also indicates the expression could be slightly improved to read epsilon' = (1 + 0.845 rho)(exp 2). Reasons are suggested as to why previous wide-angle radar sounding studies did not reproduce Robin's findings. DTIC

N94-32335 Naval Postgraduate School, Monterey, CA.
AN ANALYSIS OF IONOSPHERIC DAYGLOW FROM OBSERVATIONS OF THE NAVAL POSTGRADUATE SCHOOL MIDDLE ULTRAVIOLET SPECTROGRAPH (MUSTANG) M.S. Thesis
Antony C. Marron Dec. 1993 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277351) Avail: CASI HC A04

Middle ultraviolet spectra of the atmospheric airglow were obtained from a March 1992 rocket flight of the NPS MUSTANG instrument. These spectra are analyzed from 1900 to 3100 A, over an altitude range of 100 to 320 km. The data are modeled with computer generated synthetic spectra for the following emissions: N2 Vegard Kaplan (VK); N2 Lyman - Birge - Hopfield (LBH); and NO gamma, delta, and epsilon bands. A best fit procedure was developed. The resulting synthetic spectra agree well with obtained airglow data. Confirmation was made of the theoretical self absorption versus non-self absorption processes of the NO (0,0), (1,0), and (2,0) gamma resonance band emissions. NO self absorption is a necessary inclusion of any atmospheric nitric oxide analysis stratagem. Profiles of temperature versus altitude and NO column density versus altitude for the rocket flight are estimated. DTIC

N94-32337 Naval Postgraduate School, Monterey, CA.
THERMOSPHERIC MODELING ACCURACIES USING F10.7 AND Ap M.S. Thesis
John J. Adler Dec. 1993 72 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277355) Avail: CASI HC A04

This thesis analyzes the accuracy of the 45 day forecasted F10.7 and Ap values given by the Air Force Space Forecast Center. These forecasts are generated daily to aid many agencies in their fields of endeavor. The U.S. Space Command uses the values in orbit prediction routines by way of atmospheric density models. This thesis shows that the F10.7 forecasts are accurate from one to seven days out, then deteriorate for the latter 38 days. Conversely, Ap forecasts are less accurate from one to five days out, then improve beyond the sixth day. The effects of forecasting errors upon satellite lifetimes are then shown using the Lifetime 4.1 orbital propagation model with a Jacchia 1971 atmosphere. Propagating a typical satellite for 45 days over various configurations of altitudes and eccentricities showed that only a narrow altitude band from 250 to 325 km is affected. Regions above or below this band are not significantly affected with errors in F10.7 or Ap. DTIC

TIME-RESOLVED IR SPECTROSCOPY, ENERGY TRANSFER, AND STATE-TO-STATE COLLISION DYNAMICS OF ATMOSPHERIC SPECIES Final Report, 1 Dec. 1990 - 30 Nov. 1993
David J. Nesbitt 28 Jan. 1994 18 p
(Grant AF-AFOSR-0055-90)
(AD-A277372; AFOSR-94-0057TR) Avail: CASI HC A03/MF A01

Achievements under the AFOSR grant have been in the following areas. We have developed a new method for state-to-state collisional energy transfer in crossed molecular beams, based on high sensitivity direct IR laser absorption, and allowing absolute cross sections to be obtained by measurement of absolute number densities of the scattering species (CH4, H2O, and HF with rare gases). Polarization methods have been developed to study alignment of J states, based on rapid modulation (75 kHz) of a single mode diode laser, and used to study collisional alignment of CO2 in supersonic jets. High resolution flash kinetic spectroscopy has been used to investigate reaction kinetics of OH radical with hydrocarbons, as well as to obtain absolute quantum yields for photofragmentation of HNO3 and H2O2 at 193 and 248 nm. Pressure broadening rates of OH radical relevant to IR 'airglow' detection and characterization have been measured. A new capability has been developed

for measuring state-resolved energy transfer in 'hot atom' collisions of open shell radicals. By absolute absorbance measurements and analysis of high resolution Doppler profiles, both integral and differential cross sections to a specific final J state are obtained for Cl + HCl scattering. DTIC

SELF-CONSISTENT EFFECTS OF MAGNETOSPHERIC HYDROMAGNETIC WAVES ON RING CURRENT IONS Annual Technical Report, 1 Jan. - 31 Dec. 1993
Mary Hudson 31 Dec. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-1-0101)
(AD-A277406; AFOSR-94-0113TR) Avail: CASI HC A03

Major progress was made in obtaining an explanation for the rapid formation of new electron and proton radiation belts during the March 30, 1991 geomagnetic storm sudden commencement. Preliminary work on proton acceleration during the same event was reported at the Fall AGU meeting in December, an important feature of the simulation code that has been developed is the ability to post-process data runs after the trajectories of several hundred thousand ions or electrons have been followed through the inbound and outbound propagation time of the wave fields, which is about 100 seconds of real time. As a first step in the development of the three-dimensional MHD fluid-gyrokinetic particle hybrid code, a three-dimensional MHD version of the code in generalized orthogonal coordinates has been developed. DTIC

N94-32493 Colorado Univ., Boulder.
FORCED LIBRATION OF MERCURY AND GEODETIC DETERMINATION OF A POSSIBLE FLUID CORE Ph.D. Thesis
Xiaoping Wu 1993 181 p
Avail: Univ. Microfilms Order No. DA9320491

The possibility of determining the existence and size of a fluid core in Mercury by a combined orbiter-lander mission is investigated. Microwave Doppler and range measurements from earth to the orbiter would determine the spacecraft orbit accurately, and radio range measurements from the orbiter to the lander would determine the obliquity of Mercury and the amplitude of its 88-day forced libration in longitude. These measurements can be used to determine the fractional maximum moment of inertia of the anticipated fluid core. Consider covariance analyses are carried out to assess the performance of a simulated set of measurements consisting of 30 separate 8-hour arcs of data. Earth to orbiter ranging and Doppler tracking data with 3 cm and 1 x 10(exp -14) respective accuracies are assumed, plus orbiter to lander ranging with 1 m accuracy. The force model includes Mercury's gravity field, solar radiation pressure on the spacecraft body and on the antenna, thermal and albedo radiation from Mercury, and solid Mercury tides. The uncertainties for the estimated libration amplitude and the obliquity are shown to be 0.26 and 0.03 arcsec for the model employed. The resulting uncertainty for the fractional core moment of inertia is 0.45 percent. Moreover, the Love number k(sub 2) can be determined with an accuracy of 0.01. Based on a planet model with a rigid mantle, a homogeneous and incompressible fluid core, and a nonhydrostatic core-mantle boundary (CMB), the fluid motion and pressure fields are determined for both the free and forced motion problems. The perturbed eigenfrequencies and eigenfunctions are calculated for low degree and order inertial waves. The effect of CMB topography in the case of Mercury's forced libration is that the pressure torque on the mantle nearly equals the gravitational torque of the sun on the fluid core. Thus the mantle librates almost exactly as if it were driven by the torque of the sun on the entire planet including the core. This result means that it is still possible to detect the fluid core even with the presence of a nonhydrostatic CMB. Dissert. Abstr.

VARIATIONAL ELLIPTIC SOLVER FOR ATMOSPHERIC APPLICATIONS
Piotr K. Smolarkiewicz (National Center for Atmospheric Research, Boulder, CO.) and Len G. Margolin Mar. 1994 39 p
(Contract W-7405-eng-36)
(DE94-007725; LA-12712-MS) Avail: CASI HC A03/MF A01

We discuss a conjugate gradient type method -- the conjugate residual -- suitable for solving linear elliptic equations that result from discretization of complex atmospheric dynamical problems. Rotation and irregular boundaries typically lead to nonself-adjoint elliptic operators whose matrix representation on the grid is definite but not symmetric. On the other hand, most established methods for solving large sparse matrix equations depend on the symmetry and definiteness of the matrix. Furthermore, the explicit construction of the matrix can be both difficult and computationally expensive. An attractive feature of conjugate gradient methods in general is that they do not require any knowledge of the matrix; and in particular, convergence of conjugate residual algorithms do not rely on symmetry for definite operators. We begin by reviewing some basic concepts of variational algorithms from the perspective of a physical analogy to the damped wave equation, which is a simple alternative to the traditional abstract framework of the Krylov subspace methods. We derive two conjugate residual schemes from variational principles, and prove that either definiteness or symmetry ensures their convergence. We discuss issues related to computational efficiency and illustrate our theoretical considerations with a test problem of the potential flow of a Boussinesq fluid flow past a steep, three-dimensional obstacle. HIGH RESOLUTION PROPERTIES OF THE MARINE ATMOSPHERIC BOUNDARY LAYER
D. Cooper, W. Cottingame, W. Eichinger, P. Forman, C. Lebeda, D. Poling, and R. Thorton 1994 5 p Presented at the 21st Conference on Agricultural and Forest Meteorology, Boston, MA, Mar. 1994
(Contract W-7405-eng-36)
(DE94-006235; LA-UR-94-101; CONF-940368-1) Avail: CASI HC A01/MF A01

Los Alamos National Laboratory (LANL) participated in the Central Equatorial Pacific Experiment (CEPEX) by fielding a water-vapor Raman lidar on board the Research Vessel Vickers. The lidar measured water vapor concentration from the surface to lower tropospheric altitudes in order to support the CEPEX goal of evaluating a hypothesis regarding feedback mechanisms for global circulation models. This report describes some of the features observed within the marine Atmospheric Boundary Layer (ABL) and the lower troposphere. Data was collected continuously 24 hours per day over the equatorial Pacific from March 8th to March 21st of 1993 while in route between Guadalcanal and Christmas Island (the transect was at approximately 2 degrees south latitude). The lidar collected vertical transects of water vapor concentration up to 10 km during night operations and 4 km in the day. The vertical lidar profiles of water vapor were produced by summing the data over a period up to 600 seconds. The water-vapor Raman lidar measured the properties of the marine ABL as well as the lower and mid-troposphere. From the lidar water vapor profiles, 'images' of water vapor concentration versus altitude and date or sea surface temperature will be produced along with other products such as latent heat fluxes. The Raman water vapor lidar data will be used to better understand the role of transport and exchange at the ocean-atmosphere interface and throughout the marine atmosphere. DOE

A LONG-TERM SIMULATION OF SURFACE FLUXES AND SOIL MOISTURE
J. Kim, R. L. Lee, and M. Ek Sep. 1993 6 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-7405-eng-48)
(DE94-006661; UCRL-JC-114411; CONF-940115-24) Avail: CASI HC A02/MF A01

The heat fluxes over land surfaces play important roles in shaping atmospheric flows on various temporal and spatial scales. Fast and McCorcle showed that sea-breeze-like mesoscale circulations can develop over land surfaces of heterogeneous soil type and soil moisture. Evaporation from land surfaces is one of the major moisture sources for the summertime convective precipitation in extratropics. General circulation model studies also indicate that surface characteristics cause a significant impact on the simulated climate. DOE

We have characterized experimentally and naturally-shocked quartz (both synthetic and natural samples) by solid state nuclear magnetic resonance (NMR) spectroscopy. Relaxation analysis of experimentally-shocked samples provides a means for quantitative characterization of the amorphous/disordered silica component NMR spectra demonstrate that magnetization in both the amorphous and crystalline components follows power-law behavior as a function of recycle time. This observation is consistent with the relaxation of nuclear spins by paramagnetic impurities. A fractal dimension can be extracted from the power-law exponent associated with each phase, and relative abundances can be extracted from integrated intensities of deconvolved peaks. NMR spectroscopy of naturally-shocked sandstone from Meteor Crater, Arizona (USA) led to the discovery of a new amorphous hydroxylated silica phase. Solid state NMR spectra of both experimentally and naturally shocked quartz were unexpectedly rich in microstructural information, especially when combined with relaxation analysis and cross-polarization studies. We suggest solid state NMR as a potentially useful tool for examining shock-induced microstructural changes in other inorganic compounds, with possible implications for shock processing of structural ceramics. PARAMETERIZING ATMOSPHERE-LAND SURFACE EXCHANGE FOR CLIMATE MODELS WITH SATELLITE DATA: A CASE STUDY FOR THE SOUTHERN GREAT PLAINS CART SITE
W. Gao 1994 7 p Presented at the 5th Annual Symposium on Global Change Studies, Nashville, TN, 24-28 Jan. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE94-005109; ANL/ER/CP-80788; CONF-940131-2) Avail: Issuing Activity (Department of Energy (DOE))

High-resolution satellite data provide detailed, quantitative descriptions of land surface characteristics over large areas so that objective scale linkage becomes feasible. With the aid of satellite data, researchers examined the linearity of processes scaled up from 30 m to 15 km. If the phenomenon is scale invariant, then the aggregated value of a function or flux is equivalent to the function computed from aggregated values of controlling variables. The linear relation may be realistic for limited land areas having no large surface contrasts to cause significant horizontal exchange. However, for areas with sharp surface contrasts, horizontal exchange and different dynamics in the atmospheric boundary may induce nonlinear interactions, such as at interfaces of land-water, forest-farm land, and irrigated crops-desert steppe. The linear approach, however, represents the simplest scenario and is useful for developing an effective scheme for incorporating subgrid land surface processes into large-scale models. Our studies focus on coupling satellite data and ground measurements with a satellite-data-driven land surface model to parameterize surface fluxes for large-scale climate models. In this case study, we used surface spectral reflectance data from satellite remote sensing to characterize spatial and temporal changes in vegetation and associated surface parameters in an area of about 350 x 400 km covering the southern Great Plains (SGP) Cloud and Radiation Testbed (CART) site of the US Department of Energy's Atmospheric Radiation Measurement (ARM) Program. A CORRELATED k-DISTRIBUTION MODEL OF THE HEATING RATES FOR ATMOSPHERIC MIXTURES OF H2O, CO2, O3, CH4, AND N2O IN THE 0-2500 cm(EXP -1) WAVE NUMBER REGION AT ALTITUDES BETWEEN 0 AND 60 km
A. S. Grossman and K. E. Grant Sep. 1993 5 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-7405-eng-48)
(DE94-005136; UCRL-JC-115044; CONF-940115-18) Avail: CASI HC A01/MF A01

The main purposes of this paper are to first use the direct method of GGFP to calculate the transmission of the individual molecules H2O, CO2, O3, CH4, and N2O, plus the transmission of a mixture of all these molecules. Second, to use the G2 model for overlapping k-distributions to calculate the transmission for the CH4-N2O and H2O-CO2 systems in the spectral regions in which there are overlapping absorption features. For the wavenumber interval 0-2500 cm(exp -1) and altitude range of 0-60 km, a calculation of the atmospheric heating rates, upward fluxes, and downward fluxes will be made for each of the above cases and compared to line by line calculations. HIGH FREQUENCY ACTIVE AURORAL RESEARCH PROGRAM (HAARP) IMAGER Final Report, 29 Aug. 1991 - 29 Aug. 1993
Cyril Lance and Robert Eather 30 Sep. 1993 322 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-C-0141)
(AD-A277469; AD-E201833; PL-TR-93-2219) Avail: CASI HC A14

A low-light-level monochromatic imaging system was designed and fabricated which was optimized to detect and record optical emissions associated with high-power RF heating of the ionosphere. The instrument is capable of detecting very low intensities, of the order of 1 Rayleigh, from typical ionospheric atomic and molecular emissions. This is achieved through co-adding of ON images during heater pulses and subtraction of OFF (background) images between pulses. Images can be displayed and analyzed in real time and stored in optical disc for later analysis. Full image processing software is provided which was customized for this application and uses menu or mouse user interaction. DTIC

FINITE-ELEMENT MODELING OF THE BLOCKAGE AND SCATTERING OF LG PROPAGATION Annual Report, 1 Dec. 1992 - 30 Nov. 1993
Yu-Chiung Teng 30 Nov. 1993 58 p
(Contract F49620-93-1-0073)
(AD-A277430; AFOSR-94-0099TR) Avail: CASI HC A04/MF A01

The problem of Lg wave blockage is being investigated using finite element models of island margin, basin, and basin with an uplifted Moho to simulate wave propagation across the Barents Sea basin. Results from the first year follow. The efficiency of the crust as a Lg wave guide strongly depends on the frequency content of an impulsive source. The effects of a basin on Lg propagation also depends on the basin width and the velocity contrast between the sedimentary basin and the surrounding granitic/basaltic crust. For a high velocity contrast, the Lg wave form is significantly lengthened. The presence of an uplifted Moho alone does not appear to have a major blockage effect on Lg wave propagation. The finite element codes with the fast execution algorithm prove to be well suited as tools for the modeling purposes intended in this research. DTIC

(DA Proj. RM3-3-F-60)
(AD-A277666; NFESC-TR-2016-SHR) Avail: CASI HC A09/MF A02

This report was prepared as part of the Navy's Seismic Hazard Mitigation Program. The Navy has numerous bases located in seismically active regions throughout the world. Safe effective design of waterfront structures requires determining expected earthquake ground motion. The Navy's problem is further complicated by the presence of soft saturated marginal soils that can significantly amplify the levels of seismic shaking as evidenced in the 1989 Loma Prieta earthquake. The Naval Facilities Engineering Command's seismic design manual, NAVFAC P355.I, requires a probabilistic assessment of ground motion for design of essential structures. This report presents the basis for the Navy's Seismic Hazard Analysis procedure that was developed and is intended to be used with the Seismic Hazard Analysis computer program and user's manual. This report also presents data on geology and seismology to establish the background for the seismic hazard model developed. The procedure uses the historical epicenter data base and available geologic data, together with source models, recurrence models, and attenuation relationships to compute the probability distribution of site acceleration and an appropriate spectra. This report discusses the developed

stochastic model for seismic hazard evaluation and the associated research. DTIC

THE SPATIAL DEVELOPMENT OF THE MAGNETOSPHERIC LOW-LATITUDE BOUNDARY LAYER Ph.D. Thesis
John R. Manuel 1992 157 p
(ISBN-0-315-77418-5) Avail: Univ. Microfilms Order No. DANN77418

The low-latitude boundary layer (LLBL) comprises a large fraction of the magnetospheric boundary layer, making it a potentially important site for transport of mass, momentum, and energy from the high-speed magnetosheath plasma into the magnetosphere. I have examined, by computer simulation, the processes involved in the spatial development of a 6.4 R(sub E) (Earth radii) long section of the dayside LLBL from a thin and laminar boundary layer to a broad and turbulent one capable of significant transport. The computer simulation developed for this purpose is based on the full set of ideal magnetohydrodynamic (MHD) equations that govern the dynamics of most magnetospheric plasmas and uses a two dimensional nonperiodic simulation geometry to permit the realistic downstream development of the boundary layer. Simulations started from several realistic initial conditions all exhibit the formation of a LLBL that broadens with downstream distance, from an upstream thickness of 0.12 R(sub E) to as much as approximately 0.7 R(sub E) downstream, and reproduces many of the observed boundary layer characteristics. The broadening occurs through the action of Reynold and Maxwell stresses generated by the Kelvin-Helmholtz (KH) instability in the boundary layer which deposit momentum and energy into the LLBL. The KH instability also transports mass into the LLBL by mixing plasma across the boundary layer through continuous vortex roll ups and mergings and also appears capable of aiding diffusive transport processes by steepening density gradients at the magnetopause enough to trigger any of a number of possible diffusion processes. Simulations have also shown that the downstream development of the boundary layer may be slowed and possibly stopped in the presence of a flow-aligned component of the magnetosheath magnetic field. For example, for a magnetosheath magnetic field which is initialized to tilt 30 degrees away from perpendicular to the flow, the KH instability still develops, but fails to generate the large, merging vortices necessary to the success of the transport processes because the vortices lose kinetic energy to magnetic field distortions as they wind up the magnetic field. The magnetosheath magnetic field is thus capable of nonlinearly stabilizing the KH instability in the LLBL even though the LLBL is linearly unstable to the KH instability. Dissert. Abstr.

SIMULATION OF CO2 RELEASE AT 800 km ALTITUDE
A. Setayesh 31 Aug. 1993 22 p
(Contract F19628-90-C-0191)
(AD-A276692; RXR-93081; PL-TR-93-2177; SR-7) Avail: CASI HC A03/MF A01

The SOCRATES contamination-interaction code has been used to simulate the reactions of 0 + CO2 yields CO2(v) + O, O + CO2 - CO(v) + O2, and CO2 + H - CO + OH(v) at an altitude of 800 km in both ram and wake directions of the spacecraft. These simulations show that the radiation from these reactions can be measurable for the parameters which have been used in these calculations. The investigation carries out the simulations as much as 30 km from the spacecraft. The radiative intensity of CO(v) and OH(v) show the highest and lowest, respectively. DTIC

Laboratory-based pressure-broadening data has long provided information that is both of practical importance for technological applications and of fundamental interest for understanding molecular interactions and dynamics. During this project period the temperature dependence of the collision-broadened line widths of H2O and HDO were studied between 100 k and 600 K. Selected transitions were between 250 GHz and 500 GHz and the broadening gases were 02, N2, H2, and He. Low temperature measurements were made in a collisionally cooled cell to circumvent the limitations imposed by the low vapor pressure of the sample gas at temperatures far below their freezing points. The experimentally determined values were compared with earlier experimental and theoretical works. DTIC

THE EARTH'S CLIMATE: PAST, PRESENT, AND FUTURE [LE CLIMAT DE LA TERRE: PASSE, PRESENT ET FUTUR]

J. C. Duplessy *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 13-3 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The Earth's climate evolution is reviewed. Climate variations have occurred for about 2.9 times 10 to the 9th power years, but air temperatures have varied only within a narrow range. Mountain building and continental drift are the main factors responsible for long term climatic changes. On the 10,000 to 100,000 year scale, seasonal insolation changes determined by orbital geometry trigger the global Earth's climate. Interactions between the various components of the climatic system (ocean atmosphere cryosphere) are responsible for variations which may be very abrupt. They constitute a nonlinear response of the climatic system to slowly varying forcing factors such as insolation or atmospheric greenhouse gas concentration. ESA

The transfer of energy from equatorial to polar regions is performed either by the oceanic or atmospheric circulation. The behavior of the general atmospheric circulation in tropical regions is correlated to energy sources and wells. Satellite observations are of great help for studying the Earth's energy balance. The equations describing the radiative energy exchanges between the Earth and space are shown. The atmospheric energy wells and sources and the Hadley's-Walker energy model are explained. The kinetic description of the trade winds and of the Hadley's cell are given. The barocline instabilities and their influence over general atmospheric circulation are studied. ESA

GENERAL OCEAN CIRCULATION [CIRCULATION GENERALE OCEANIQUE] **c48**

P. Delecluse *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 81-9 In FRENCH Prepared in cooperation with Paris VI Univ., Fran ce and Office de la Recherche Scientifique et Technique Outre-Mer (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

Physical properties of the ocean and the atmosphere are compared. The energy exchanges between both fluids are reviewed. Forces acting in the ocean are presented and the set of governing equations is established. The study is carried out for cases when the ocean is forced by the wind. The general circulation is discussed with the thermocline structure under thermohaline stresses. The North Atlantic Deep Water belt is described to illustrate space and time scales. The study of particle trajectories of the North Atlantic Deep Water belt shows that numerical modeling is in agreement with Gordon's Scheme. The results show that global oceanic circulation can be well understood by numerical models, but difficulties arise from the lack of observational data. ESA

CLIMATOLOGIC FLUX IN TROPICAL OCEAN [FLUX CLIMATOLOGIQUES EN OCEAN TROPICAL] **c48**

S. Planton *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 99-120 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The air-sea flux climatologies are based on the application of empirical to atmospheric parameters and sea surface temperatures. The calculation of the meridional heat transport in the ocean inferred from the surface net heat flux reveals the discrepancies between different available estimates. These discrepancies are notable in the climatological estimates of the energy budget of the Warm Pool of the western tropical Pacific. They reflect uncertainties related to observation errors, errors in the used empirical formulae or sampling errors. The overall uncertainty of the annual mean net heat flux is about 40 W/sq m for the Tropical Pacific. New flux climatologies with expected lower uncertainties are based on the use of satellite data. Fluxes are retrieved either through statistical method or through a physical modeling. ESA

DYNAMIC CLIMATOLOGY OF WEST AFRICA [CLIMATOLOGIE DYNAMIQUE DE L'AFRIQUE DE L'OUEST]

P. deFelice (Ecole Polytechnique, Palaiseau, France.) *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 153-169 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

Mean meteorological fields are displayed on several tropospheric levels for Summer and Winter. The following West Africa perturbation phenomena are described: Winter cold waves, Summer east waves and squall lines. The differences which distinguish tropical and equatorial zones meteorology are summarized. The velocity, temperature and geopotential mean fields are calculated from Meteosat data and analysis performed by the European center of mean term meteorological predictions. The cold advection phenomenon which occur during cold seasons is described. Three criteria describing the intertropical front are reviewed. Future developments in African climatology studies are considered. ESA

N94-30989 Office National de la Meteorologie, Algiers (Algeria).

SOME ASPECTS OF THE DROUGHT IN NORTH AFRICA AND IN THE MEDITERRANEAN BASIN [QUELQUES ASPECTS DE LA SECHERESSE EN AFRIQUE DU NORD ET DANS LE BASSIN MEDITERRANEEN]

Mohammed Kadi *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 171-198 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The results of studies concerning recent precipitation data from the Mediterranean basin are discussed. The data shows that meteorological drought is more apparent in the 1980's. However, chronic disruptive situations were observed. The North Atlantic oscillations, the sea surface temperature in the North Atlantic Ocean, the so called Mediterranean oscillations and the strength and position of some atmospheric circulation are potential indicators of the meteorological aspects of drought for this basin. In the context of climate change, more observations and research is needed on this phenomena because data on drought in this region remain rare. ESA

DYNAMICS IN THE TROPICS AND SYNOPTIC DISTURBANCES

Daniel L. Cadet *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 201-214 (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The importance of tropical perturbations of synoptic scale is discussed within the framework of the general circulation of the tropics. It is based on the concept of energetics. The scale organization of convection in the tropical belt, which is occurring on a small scale and can give rise to the large scale east-west cells and the upper troposphere tropical jet, is explained. The tropical perturbations affecting different regions of the tropics are described. The major differences between them is discussed and the common features are emphasized. The perturbations affecting West Africa and the Indian subcontinent are described. ESA

LOW FREQUENCY VARIABILITY OBSERVED IN THE TROPICAL ATLANTIC OCEAN [VARIABILITE BASSE FREQUENCE OBSERVEE DANS L'OCEAN ATLANTIQUE TROPICAL] **c48**

Alain Morliere (Paris VI Univ., France.) *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 215-231 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The yearly and seasonal variability of parameters describing the upper layers of the Atlantic tropical ocean are considered. These parameters play a role in the ocean-atmosphere interactions and the most important one is certainly the sea surface temperature. Equilibrium changes between the heat flow through the sea's surface, the horizontal or vertical advection and mixing layer phenomena induce temperature changes at the ocean's surface. The variability of the tropical Atlantic sea's surface can be easily correlated to wind variations and is controlled by seasonal signals. Yearly changes similar to those concerning El Nino and eigenvalue oscillations controlled by meridian signals are also observed in the Atlantic. ESA

N94-30992 Centre National de Recherches Meteorologiques, Toulouse (France).

TROPICAL SQUALL LINES [LES LIGNES DE GRAINS TROPICALES]

J.-L. Redelsperger (Centre National de la Recherche Scientifique, Toulouse, France.) *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 233-259 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The present knowledge on tropical squall lines is summarized. The atmospheric convection plays a major role in the general atmospheric circulation and, in particular, in tropical and intertropical regions. The rainfalls produced by convective atmospheric motions are essential for life and climate evolutions. The analysis of annual rainfall as a function of the latitude shows the effect of: cloud systems, tropical squall lines, tropical cyclones, convection during the day, and extratropical cyclones. Several international cooperation experiments were carried out to study tropical rainfall systems. Two of them are considered; The GATE (Global Atmospheric program's Atlantic Tropical Experiment) and the COPT81 (French acronym for deep tropical convection, 1981). ESA

THE CLIMATE OF THE MEDITERRANEAN BASIN: ITS SENSITIVITY TO GLOBAL CHANGE

Manuel deCastro *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 261-280 (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The peculiarities of the climate in the Mediterranean basin, due to the geographic location and to the presence of a warm sea enclosed and surrounded by a complex orography, are discussed. The interaction of general circulation with Mediterranean basin climate is studied. The aim was to underline the fact that in this particular geographical area any attempt of climate forecasting requires both improvements to the general circulation models and better knowledge of the connection between local and regional meteorological processes and the nature of large scale circulation. In this respect, specific studies are required in the area. Studies considered to be of special importance are proposed. ESA

EFFECTS OF THE DEEP TROPICAL CONVECTION IN THE LARGE SCALE ATMOSPHERIC FLOW [LES EFFETS DE LA CONVECTION PROFONDE TROPICALE SUR L'ECOULEMENT ATMOSPHERIQUE DE GRANDE ECHELLE]

P. Bougeault *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 281-299 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

A global approach to study large tropical clouds is presented. It is called the convection parameterization method. A scale analysis of the tropical zone motions and the principles of cloud convection are discussed. The thermodynamic variables, the temperature and moisture profiles in convective clouds and a convective ascendence model are reviewed. It is shown how, by applying the global thermodynamic balance method, the effects can be experimentally assessed. The following approaches used in convection parameterization in climate models are summarized: the Kuo approach, the Arakawa Schubert calculation, the Bourgeault mass flow scheme. ESA

THE OCEAN-ATMOSPHERE INTERACTIONS IN THE MEDITERRANEAN SEA [LES INTERACTIONS OCEAN-ATMOSPHERE EN MEDITERRANEE] **c48**

J. P. Bethoux *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 301-312 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The Mediterranean Sea is a plot area for air-sea interaction studies and can be considered as a small scale model for studying different phenomena of the terrestrial ocean. In particular, climate drives concentration basin dynamics and dense water formation. Marine data allows hypothesis and models for studying paleoclimate or recent climate changes. The Mediterranean Sea thermal balance shows that the water evaporation losses are superior to fresh water gains. The east and west Mediterranean sea zones are concentration basins and their water dynamics are the result of interactions with the atmospheric circulation. The dense water thermal changes in the west Mediterranean zone can be an indicator of the greenhouse effect increase. ESA

RADIATION/REMOTE SENSING: REVIEW OF THE PRINCIPAL DEFINITIONS [RAYONNEMENT/TELEDETECTION: RAPPEL DES PRINCIPALES DEFINITIONS] **c43**

G. Dedieu (Centre National de la Recherche Scientifique, Toulouse, France.) *In its* Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 315-32 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The following concepts which allow studying the electromagnetic radiation phenomena are discussed: the solid angle, the black body radiation, the natural body's thermal emissions. The differences between bulk and surface reflections is stressed. The equation of the spectral two dimensional reflectance and that of the albedo, the ratio between emitted and reflected radiation powers, are given. The basic principles for calculating the radiation energy balance are summarized. Radiometric measurements of an extended light source are carried out. Terrestrial luminosity at long and short wavelengths is studied. ESA

SPACE EQUIPMENT FOR EARTH OBSERVATIONS [LES INSTRUMENTS SPATIAUX D'OBSERVATION DE LA TERRE] **c19**

Marc Leroy *In its* Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 329-38 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The operation principles of space equipment are summarized. Earth observation from space has known an important development these last years and will probably grow even more rapidly in the short term. A wide variety of space instruments, active or passive, in the optical or microwave range can be found. The principles of measurement of these space instruments are reviewed. The notion of temporal resolution is made clear through the description of the orbits used in the field of Earth observation. The link between instrument measurement and input radiance is clarified. ESA

MODELING THE INTERACTION BETWEEN SOLAR RADIATION AND TERRESTRIAL SURFACES

Michel M. Verstraete and Bernard Pinty *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 413-430 (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The reasons for modeling the interaction between solar radiation and terrestrial surfaces, the required approximations, and the way they affect the level of representativity of the models, and the principles and rationale of model inversion against observed data, are reviewed. Significant progress was achieved towards the design of realistic models of bidirectional reflectance of natural surfaces, and this effort is a major element in the stragegy to retrieve quantitative information from satellite remote sensing data. Important limitations remain in model design, and the lack of comprehensive data sets of reflectances, coupled with exhaustive descriptions and measurements of the optical and structural properties of the observed surfaces, make it difficult to validate existing models. In the mean time, urgent environmental issues require immediate attention, and more empirical approaches may be necessary. ESA

Meteorological satellites provide two kinds of atmospheric products in an operational way: cloud track winds and temperature and humidity profiles. These products have a limited accuracy but are useful in tropical areas. The content of the satellite information allows the study of parameters such as the elements of the radiative budget, the cloudiness characteristics, and precipitations. The useful methodologies are reviewed and illustrated with examples of applications to specific studies of tropical phenomena. The perspectives offered by new space sensors and necessary research developments are reviewed. ESA

THE SURFACE PARAMETERS: REMOTE SENSING OBSERVATIONS AND CLIMATOLOGY APPLICATIONS [LES PARAMETRES DE SURFACE: OBSERVATION PAR TELEDETECTION ET APPLICATIONS EN CLIMATOLOGIE]

Jean-Pierre Lagouarde *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 447-465 In FRENCH (For primary document see N94-30981 09-47)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The state of the earth surface determines the exchange process between the soil and the atmosphere, which have a certain influence over climate phenomena. Several parameters, which are suitable indicators of surface conditions, can be observed by satellites. Some examples of remote sensing potentialities for studying global vegetation and climate phenomena, in particular over tropical zones, are presented. Several methods were developed for applying teledetection data in climate studies. Some of these data can be used directly, such as those for albedo cartography in general circulation meteorology. Algorithms were developed for cases where data

has to be transformed, for instance, rain or evaporation mapping from surface temperature data. However, improvements of algorithms and of the accuracy of present satellite data are still needed. ESA

RADAR MEASUREMENTS [MESURES RADAR] **c32**
Frank Roux *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 467-494 In FRENCH (For primary document see N94-30981 09-47)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The radar operation principles, some applications, and data analysis techniques are summarized. Special attention is given to meteorological, Doppler, polarization diversity, and wind profiling radars. The design parameters and the radar equation and historical facts are summarized. Some of the latest developments on meteorological radars are related to onboard and space radars. One of the difficulties is the attenuation of satellite emissions by rain, which leads to the development of reliable data processing algorithms. The electronic radar components acquired suitable reliability and the data processing techniques allow in most cases accurate quantitative results. ESA

Dust particles or desert aerosols come from arid and half arid zones, in particular from the Sahara, which is responsible for 25 percent of the total amount of aerosols. During desert storms, the dust can be carried by the wind and reach the Atlantic sea surface and the Caribbean. For accurately modeling dust transport phenomena, the dust plumes to be studied have to be localized and their evolution has to be daily and yearly described. Present satellite sensors do not allow continuous sensing of the motion of dust clouds. The use of satellite imagery for studying aerosol characteristics and dust transport phenomena is summarized. BEHAVIOR AND DYNAMICS OF TROPICAL FORESTS AND SAVANNAS [FONCTIONNEMENT ET DYNAMIQUE DES FORESTS ET SAVANES TROPICALES] **c43**
J. C. Menaut *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 527-546 In FRENCH (For primary document see N94-30981 09-47)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The tropical zones cover approximately one third of the earth's land surface. The tropical forests and the savannas show similar characteristics. This particularity allows the tropical African forest to be used as a model for studying the world's tropical forests. The general characteristics and the behavior of the savanna's ecosystem are dicussed. The dynamics of the savanna's ecosystem mainly depends on grass/tree regulative exchanges and on the soil water content. The importance of applying a model for studying soil, vegetation, and atmospheric interactions is explained. The effects of the following phenomena are discussed: atmospheric carbon dioxide content, temperature increase, rainfall distribution, soil occupation/use, and the disturbances caused by natural or human activities. Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The ecosystem characteristics, the main elements of carbon balance in forests, and data from well known regions are given. However, most results must be taken as an indication instead of as the absolute truth: up to now, there is no ecosystem where all the required parameters and variables are measured. In order to improve the understanding of the forest ecosystems and the effect of several phenomena, research programs are focalized into two directions: modeling present forest ecosystem; studying, modeling, and simulating the effect of global changes on the balance of carbon of forests. In order to understand the role of trees in CO2 formation it is necessary to pass from local to global scale, which requires the use of satellite remote sensing technology. ESA

CLIMATIC EVOLUTION AND DESERTIZATION [EVOLUTION CLIMATIQUE ET DESERTISATION]

H. N. LeHouerou *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 639-668 In FRENCH (For primary document see N94-30981 09-47)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

The concept of desertization, or the irreversible growth of new desert areas onto arid zones, is discussed. The phenomenon is characterized by the gradual disappearance of vegetation, which becomes concentrated nearby water sources. Several scenarios for explaining the desertization phenomena which take into account the effects of CO2 pollution and the increase of about 3C of the Earth's temperature, are summarized. Up to now, these scenarios are not reliable concerning predictions of seasonal changes. It is shown that the albedo has no effect on the climate, at least for local effects. The human activities and the zones of high population densities are under continuous desertization danger. New technologies such as remote sensing are valuable tools for helping the environment management. ESA

THE OZONE AND THE PHYSICO-CHEMICAL PROCESSES IN TROPICAL REGIONS [OZONE ET PROCESSUS PHYSICO-CHIMIQUES DANS LES REGIONS TROPICALES] **c45**
Gerard Megie (Paris VI Univ., France.) and Gerard Ancellet (Paris VI Univ., France.) *In* CNES, Subtropical Climates and Their Evolution: From Space-Based Observation to Modelling Oct. 1993 p 669-685 In FRENCH (For primary document see N94-30981 09-47)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111, rue Nicolas-Vauquelin, 31100 Toulouse, France)

Population growth, industrial production, and transportation induce changes in the chemical composition of the atmosphere, which disturb the Earth's environment. The tropospheric ozone content is correlated to climate changes. The processes controlling the distribution of ozone in the troposphere are discussed. The ozone percentage in tropical regions is highly dependent on the presence of ozone wells (by photolysis and the rupture of OH and HO2 radicals) and on the biomass burning processes. Experimental results demonstrate the corrrelation between the low troposphere's composition and the emission of burned savanna products. ESA

Modeling the dynamics of the terrestrial biosphere proceeds in four steps: a calculation of the area which can be colonized by vegetation; a parameterization of the exchanges of energy, water, momentum, carbon dioxide, or other physical and chemical quantities; a simulation of local ecological dynamics; and a description of migratory processes. Seven generic models of ecological dynamics, namely, probabilistic, inferential, threshold, statistical, response surface, ecophysiological, and mechanistic models, are described. Existing vegetation schemes are not suited to describe the continental biosphere in a general circulation model. Scaling issues accociated with the representation of migratory processes are also discussed. The CFL (Courant, Friedrichs, and Lewis) stability criterion insures that a model does not transfer atmospheric information more rapidly through space than time. Conversly, a vegetation model should give the landscape enough time for movements of vegetation across the landscape to be properly registered. The migration criterion guarantees that this is the case. A coupled climate/vegetation model respects the criterion when the ratio of its climatic and vegetation space is approximately five orders of magnitude smaller than the ratio of its time scales. ESA

A COMPARISON OF PREDICTORS FOR FIRST-GUESS WIND SPEED ERRORS
Donald P. Gaver and Patricia A. Jacobs Dec. 1993 36 p
(AD-A276460; NPS-OR-93-020) Avail: CASI HC A03/MF A01

Numerical meteorological models are used to assist in the prediction of weather. Each run of a numerical model produces forecasts of meteorological variables which are used as preliminary predictions of the future values of these variables. These initial predictions are referred to as first-guess values. Estimation of the mean-square first-guess error is required in the optimal interpolation process in the numerical prediction of atmospheric variables. Several predictors for the mean-square error of the first-guess wind speeds are studied. The results suggest that prediction using observed covariates tend to be better than those using first-guess covariates. However, observed covariates are not always available. Predictions using first-guess covariates are better at the 250 mb level than the 850 or 500 mb levels. Of those first-guess covariates studied, first-guess wind speed appears to be the best. DTIC

REGIONAL SOURCES OF ERROR GROWTH IN THE NATIONAL METEOROLOGICAL CENTER'S MEDIUM-RANGE FORECAST MODEL Ph.D. Thesis
Carolyn A. Reynolds 1993 223 p
Avail: Univ. Microfilms Order No. DA9326932

The full spatial structure of systematic and random error growth in the National Meteorological Center's Medium-Range Forecast Model is investigated in an effort to identify the sources of error growth. The random error growth is partitioned into two types: external error growth, which is due to model deficiencies, and internal error growth, which is the unstable growth of errors in the initial conditions. Data from winter 1987, summer 1990, and winter 1992 are compared to assess seasonal variations in regional error growth, as well as to forecast model improvement. The tropical upper-tropospheric easterly bias in the forecast model is strongest in the regions of the upper-tropospheric westerlies. The structure of the evolution with forecast time of the U-field variance is consistent with the theory of stronger meridional propagation of extratropical disturbances where the U-field is westerly and energy accumulation where delta(U)/delta(x) is negative. The spatial structure of the external error growth in the extratropics reveals that the representation of orography in the model is inadequate. There is evidence of enhanced external error growth over the Rockies, Himalayas, and Antarctica. In the tropics, high external error at the 200 mb level is closely associcated with deep convection. There is evidence of significant model improvements in the tropics at the 850 mb level between 1987 and 1992. Internal error growth in the mid-latitudes is strongly associated with blocking phenomena, especially over the North Atlantic and Europe. In the tropics, there is some evidence of internal error accumulation in regions where delta(U)/delta(x) is negative. The results of this study are physically meaningful and in agreement with previous predictability studies, as well as current knowledge of forecast model deficiencies, while at the same time, providing new information about the full spatial and temporal distributions of forecast errors. Dissert. Abstr.

BOUNDARY-LAYER CUMULUS OVER LAND: SOME OBSERVATIONS AND CONCEPTUAL MODELS
R. B. Stull 1993 16 p Presented at the ECMWF Workshop on Boundary-Layer Clouds, Reading, England, 8-11 Jun. 1993
(Contract DE-FG02-92ER-61361)
(DE93-040820; CONF-9306252-1) Avail: CASI HC A03/MF A01

Starting in 1980, the Boundary Layer Research Team at the University

of Wisconsin has been systematically studying the formation and evolution of nonprecipitating boundary-layer cumulus clouds (BLCu) in regions of fair weather (anticyclones) over land (Stull, 1980). Our approach is to quantify the average statistical characteristics of the surface, thermals, boundary layer, and clouds over horizontal regions of roughly 20 km in diameter. Within such a region over land, there is typically quite a variation in land use, and associated variations in surface albedo and moisture. DOE

N94-31743 Illinois Univ., Urbana-Champaign.
FIELD STUDIES OF RAINDROP OSCILLATIONS WITH APPLICATIONS TO RADAR METEOROLOGY Ph.D. Thesis
Ali Tokay 1993 181 p
Avail: Univ. Microfilms Order No. DA9329183

The characteristics and causes of raindrop oscillations were studied from two field experiments in Hawaiian and Illinois showers. The former experiment (HaRP) focused on the onset of raindrop oscillations as well as oscillations frequencies of small raindrops, whereas the latter experiment (ISWS) had a broader purpose to investigate the oscillation characteristics of moderate-to-large sized raindrops including amplitudes as well as frequencies, and oscillation causes. Raindrop oscillations were found to start at a diameter of d = 1.0 to 1.1 mm in both HaRP and ISWS experiments, consistent with 1991 laboratory observations of Beard, Kubesh, and Ochs and with the expected onset of eddy shedding. Most of the oscillation frequencies (greater than 95%) were near the fundamental harmonic (f2) with only a few observed near the first harmonic (f3) in both experiments. The oscillation frequencies around the fundamental harmonic showed a sized dependency that crossed the theoretical value for f2 at about d = 1.5 to 1.6 mm. The oscillation amplitude measurements determined from the vertical extent of the dash streaks showed good agreement with the 1988 data of Sterlyadkin, whereas the oscillation amplitudes estimated from the distortion indicated somewhat larger values of d greater than 2 mm. Eddy shedding was found to be the most likely cause of small raindrop oscillations because of the onset oscillations near 1.0 mm and weak forcing by drop collisions, turbulence, and wind shear. The influence of raindrop oscillations on dual-polarization radar parameters was investigated for the observed and theoretical size distributions using axis ratios based on different sets of calculations and measurements. Differential reflectivity (Z sub DR) decreased by as much as 0.74 dB from its value for non-oscillating raindrops. Similar change caused by raindrop oscillations were also found for the other dual-polarization parameters, such as the circular and linear depolarization ratios (CDR, LDR), differential phase shift, and differential specific attenuation. Dissert. Abstr.

N94-31775 Utah State Univ., Logan.
THE PROPERTIES OF SUNFLECKS IN A FLEXIBLE PLANT CANOPY, AND THEIR RELATIONSHIP TO TURBULENCE Ph.D. Thesis
Hongliang Tong 1992 175 p
Avail: Univ. Microfilms Order No. DA9316793

The properties of sunflecks within alfalfa canopies and their relationship to atmospheric turbulence above the canopies were quantified. Transient light environment in an alfalfa canopy was observed being highly dynamic, lasting from fractions of seconds to minutes in duration. Both probabilistic analysis and autocorrelation analysis indicate that the mean duration of sunflecks ranges from 0.1 to 1.6 seconds with most frequent sunflecks having durations of 0.2 to 0.8 seconds. Power spectral analysis suggests that winds have significant influences on the properties of sunflecks in the alfalfa canopies. Calculated power spectra of photosynthetically active radiation (PAR) time series within the canopies show clear linear relationships with the mean wind speeds and the spectra of vertical velocity measured 16 m above the canopies. This implies that the properties of sunflecks may be evaluated from the measured properties of turbulence. Results also show that the total variances of the PAR time series increase with increased wind, and the enhancement in variance is more apparent in lower canopy as wind increases. This suggests that the wind-induced movement of plants can reduce the vertical light gradient with canopy depth. Also, frequency distributions of sunfleck irradiance were found to disobey the normal distribution laws, but to be skewed. The skewness is affected by both canopy depth and wind. Smaller canopy depth and stronger winds can cause larger skewness. An attempt was made to use the beta distributions to simulate the PAR irradiance distributions, and the simulated results seem acceptable. The PAR spatial series were also characterized. Spatial power spectral analysis suggests that small-scale spatial heterogeneity is a predominant feature of light environment in alfalfa canopies, and lower solar elevation seems to decrease the spatial variability. In addition, similar analyses were conducted for an aspen canopy. The power spectra of the PAR time series measured within the aspen crown indicates that wind-induced leaf flutter can yield rapid sunflecks of 6 Hz in frequency. Dissert. Abstr.

NUMERICAL SIMULATIONS OF MONSOON RAINFALL WITH THE NRL/NCSU REGIONAL NESTED GRID MODEL Ph.D. Thesis
Kirankumar Venkata Alapati 1993 209 p
Avail: Univ. Microfilms Order No. DA9316598

The short-range prediction of monsoon circulations and associated weather is a challenging problem. Two important physical processes which affect the dynamics as well the thermodynamics of the monsoon are the cumulus convection and the energy and the mass transfer in the atmospheric boundary layer. From the modeling point of view, horizontal and vertical resolutions, numerical techniques and data preparation are important components. A limited area numerical model with different boundary layer and cumulus parameterizations has been developed to simulate various physical processes and rainfall associated with the Asian summer monsoon. The model developed for this research is based on a version of the Naval Research Laboratory's nested grid model. Two different cumulus parameterization schemes, one developed by Kuo and the other by Betts-Miller, are used to simulate the monsoon rainfall during three different periods of the monsoon during which rainfall was moderate to heavy. Results indicate that the monsoon processes and associated rainfall are better predicted with the Kuo scheme. Uncertainties present in the adjustment parameter used in the Betts-Miller scheme lead to poor predictions. These results indicate necessity for further testing of the Betts-Miller scheme for the monsoon region. Model forecast showed considerable sensitivity to the sea surface temperature distribution. When observed sea surface temperatures are used, predicted rainfall is considerably higher than with the climatological values. Model results also indicated higher rainfall rates when a diabatic initialization scheme is used. With an increased vertical resolution in the boundary layer and better boundary layer physics, the sixteen layer model predicted significant diurnal variation of the height of the boundary layer over land and very little variation over the oceans. Also, forecast errors in the predicted fields are reduced particularly in the lower troposphere. Circulation patterns and the temporal and spatial distributions of rainfall are also better predicted with increased vertical resolution. Dissert. Abstr.

RADAR RAINFALL MEASUREMENTS FROM SPACE Ph.D. Thesis
Duc Cong Kieu 1992 348 p
Avail: Univ. Microfilms Order No. DA9327538

Existing spaceborne rain-rate retrieval algorithms have unreasonable assumptions, and usually yield unrealistic and/or inaccurate rain-rate estimates. The relative errors in the rain-rate estimates of existing algorithms are typically larger than 50 percent. Practical constraints, and spatial and temporal variability of rain have made the potential rain rate estimation from a spaceborne platform very erroneous. The robust rain-rate retrieval (RRR) algorithm accurately extracts rain-rate profiles, using information from active and passive microwave sensors. Simulation results show that the total error in the RRR algorithm is within 20 percent. The RRR algorithm binds the rain-rate and rain-parameter estimators with guess intervals, utilizes radar properties of rain and concepts from existing rain-rate retrieval algorithms to further refine the rain-rate estimators, employs an adaptive weighted nonlinear least-squares technique, accounts for the presence of melting layers, and robustly produces unique and accurate rain-rate profiles. Measurement of rainfall from space will provide climatological data over regions where rain gauges are sparse, particularly over the oceans and developing countries. The planned Tropical Rainfall Measuring Mission (TRMM) radar will scan from side to side (i.e., the SSS mode). The proposed conical scanning (CS) mode offers many advantages over the side-to-side scanning (SSS) mode. For example, the high surface-clutter interference near vertical in the SSS mode is absent in the CS mode. The CS mode can be attained in three ways. They involve the use of a mechanically scanned parabolic-reflector antenna or fixed array, a single large fixed vertical electronically space-fed antenna, and two small tilted electronically

scanned space-fed antenna. The work here studied the feasibility of space-fed array (i.e., lens arrays and reflect arrays), active arrays, parabolic reflectors for the rain radar in the CS mode. Dissert. Abstr.

SCATTEROMETER WIND-SPEED EXPONENTS: A REVIEW AND SAXON 35-GHz MEASUREMENTS

Xiao-Ping Wang Aug. 1993 45 p

(Contract N00014-89-J-3221)

(AD-A276568; CRINC/RSL-TR-8621-2) Avail: CASI HC A03/MF A01

Wind exponents Gamma are very important in the study of radar scattering cross-section under ocean-surface conditions. Most experiments apply the ordinary least-square regression (OLR). However, OLR accounts for error in only one variable in the regression, and therefore the results of OLR may not be statistically correct. In contrast, the orthogonal regression (OR) provides a good way to estimate two correlation variables (x,y) when both of them have errors. The best results are obtained if x and y have similar scales. Our study shows that OR has agreement with OLR when x is perfectly known without errors. Otherwise, OR and OLR have different results. For example, SAXON-FPN experiment (35 GHz) data demonstrates that orthogonal regression (OR) and ordinary linear regression (OLR) methods have similar wind exponent, Gamma, if the wave and the wind directions are same. If however, the directions are not the same, the estimates disagree. In this case, the estimate of Gamma from OR and OLR methods. Thus, it is seen that the wind exponent Gamma, has a highest value in both OR and OLR methods. Thus, it is seen that the wind exponent, Gamma, has a highest value when the wind direction and the wave direction are normal to the radar. DTIC

CUMULUS CONVECTION PARAMETERIZATION AND NUMERICAL MODELLING OF MOIST ATMOSPHERES Ph.D. Thesis

Nilton de Oliveira Renno 1992

Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

A hydrological cycle is explicitly included in a one-dimensional radiative-convective equilibrium model which is coupled to a 'swamp' surface and tested with various cumulus convection schemes: the Moist Convective Adjustment scheme (Manabe et al, 1965), the Kuo (1974) scheme, the GISS (1974) Model scheme, the GISS (1983) Model II scheme, and the Emanuel (1991) scheme. Our results show that when the flux of incoming solar radiation is above a critical value -- dependent on the choice of the cumulus convection scheme -- equilibrium is not possible (a runaway greenhouse occurs). When the atmosphere's relative humidity is kept fixed at climatological values, the runaway greenhouse is inhibited. Furthermore, while the mass flux schemes (GISS (1974), GISS (1983), and Emanuel (1991)) produce an abrupt runaway greenhouse -- which occurs through a finite amplitude instability generated by the interaction of infrared radiation fluxes with detrained water vapor at the level of neutral buoyancy -- the other schemes produce a smooth transition to the runaway greenhouse. In addition, our results show that the Moist Convective Adjustment scheme breaks down when the runaway greenhouse is approached, and that the various cumulus schemes tested produce a decrease in the relative humidity of the middle-upper troposphere when the atmosphere's CO2 content is doubled. These schemes are not consistent with each other since they not only lead to different critical solar forcing for a runaway greenhouse to occur, but also produce very different water vapor profiles in the equilibrium atmosphere and have different lapse-rate feedbacks. Finally, using the scheme proposed by Emanuel (1991), we show that the atmospheric water vapor content and, therefore, the sensitivity of the equilibrium temperature to changes in the solar forcing, as well as the critical solar forcing in order for the runaway greenhouse to occur, depend crucially on the microphysics of cumulus convection. These results indicate that a physically-based cumulus convection scheme is of crucial importance in climate simulations, and that a poor cumulus convection scheme can produce artificial sensitivities in numerical simulations of moist atmospheres.

SHORT TERM TELECONNECTIONS ASSOCIATED WITH AN INDIVIDUAL TROPICAL CYCLONE M.S. Thesis

Stephen C. Woll Dec. 1993 138 p

(AD-A277210) Avail: CASI HC A07/MF A02

The short term teleconnections associated with an individual western Pacific tropical cyclone were investigated using an atmospheric general circulation model. The general strategy was to use the GCM, in combination with several tropical cyclone bogusing procedures, to isolate the effects on the global circulation of the tropical cyclone. The bogusing procedures were used to alter the tropical cyclone in the initial conditions for the model. The primary modeling experiments involved using the tropical cyclone bogusing procedures to include or exclude the tropical cyclone from the initial conditions. The difference between model results that contained the tropical cyclone and those that did not were used to analyze the global response to the tropical cyclone. These results showed a strong and persistent teleconnection response in the extratropical Northern Hemisphere. This response was mainly evident in slowly propagating Rossby waves in the 200 mb height field. Examinations of the teleconnection mechanisms showed that the east Asian-north Pacific jet played a major role in the development of the teleconnection. In particular the following occurred: (1) the 200 mb height responses showed a consistent relationship with the jet; (2) the jet acted as a waveguide for the Rossby wave energy; and (3) the regions of potential barotropic instability which flank the jet were often colocated with areas of wave amplification. THE EVOLUTION OF JET FEATURES DURING THE 1993 EAST COAST WHITE HURRICANE: A CASE STUDY USING THE GLOBAL SPECTRAL MODEL M.S. Thesis

Anton J. Kraft Dec. 1993 179 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A277217) Avail: CASI HC A09

During the period of 12-14 Mar. 1993 a major snow storm, later described as a White Hurricane, formed over the Gulf of Mexico, moved east-northeast across the Florida panhandle, and then headed northeast along the eastern seaboard. The extreme weather produced by this storm was responsible for 243 deaths and $1 billion in property damage. Because the storm was accompanied by unusually strong jet streaks, a diagnostic of the storm kinetic energy contents and generation of kinetic energy was undertaken. The vertically integrated kinetic energy (IKE) and vertically integrated generation of kinetic energy (IGK) are shown to be effective tools in determining how jet streaks influenced the development of this storm. Specifically, IKE can indicate geographically where jet streak maxima are located, whereas IGK can provide a measure of the effect of transverse circulations aloft. In addition, IGK combined with IKE can indicate if the jet streak is weakening or strengthening. The data used in this case study were primarily the National Weather Service's Global Spectral Model aviation forecast and analysis. These data were further interpolated for use in VISUAL, which is a meteorological diagnostic and display program developed primarily at the Naval Postgraduate School. DTIC

ESTIMATION AND ANALYSIS OF CLIMATE-SCALE RAINFALL OVER THE TROPICAL PACIFIC Ph.D. Thesis

Wesley Keith Berg 1993 216 p

Avail: Univ. Microfilms Order No. DA9320396

The relatively recent advent of spaceborne passive microwave technology, which has the ability to see beyond the cloud tops viewed by traditional visible and infrared sensors, has provided new prospects for global rainfall estimation. Using data from the Special Sensor Microwave/Imager (SSM/I) a database of monthly rainfall estimates has been produced over the global oceans for a three and one half year period from July 1987 through December 1990. Comparisons with in situ observations from a group of Pacific atoll rain gauge sites were used to calibrate the monthly estimates. These estimates were then compared to monthly rainfall estimates made from visible and infrared satellite observations. Based on this comparison, the SSM/I estimates were found to be as good or better than the other techniques, although the sampling provided by the SSM/I was determined to be the major limiting factor. A quantitative assessment of the errors revealed the uncertainty in the monthly SSM/I rainfall estimates averaged over 2.5 degrees latitude/longitude bins to be on the order of 20 to 25 percent of the monthly values. A subsequent analysis of the monthly SSM/I rainfall time series revealed both the major

features of the precipitation distributions and the seasonal fluctuations to agree with expected values. In addition, evidence of a strong interannual signal corresponding to the 1986-87 El Nino and the ensuing 1988-89 La Nina was found. Finally, an EOF analysis of the resulting monthly rainfall time series was performed which showed strong seasonal and interannual signals as well as evidence of variability over semiannual and intraseasonal time scales. SELECTION OF CLIMATE STATION DATA USING CLUSTERING AND TRIANGULATED IRREGULAR NETWORK TECHNIQUES Technical Report, Mar. 1992 - Jan. 1993
Kevin R. Slocum Oct. 1993 32 p
(DA Proj. 4A1-62784-A-855)
(AD-A276658; TEC-0041) Avail: CASI HC A03/MF A01

This report presents a methodology of adding an elevation variable to the process of selecting climate station data for computer modeling. Various techniques are used in this method which include statistical correlation of climatic variables, clustering of climate station data, and development of a triangulated irregular network (TIN) internal graphic layer with nodes representing climate station locations. Improvements to the climate station data selection process are documented. DTIC

(AD-A277384; AFOSR-94-0112TR) Avail: CASI HC A03

This research utilizes satellite and surfaced derived cloud observations to improve our diagnostic capability of areal cloud coverage. In particular, a new relationship between relative humidity, vertical velocity, and cloud cover has been tested. Results of this research will be used to complement existing cloud cover parameterization in both regional scale and global scale models. Improved forecasts of fractional areal of cloud cover is the number one meteorological research priority of the U.S. Air Force. DTIC

THE INFLUENCE OF CUMULUS PARAMETERIZATION ON MODEL FORECASTS OF RAPID OCEANIC CYCLOGENESIS M.S. Thesis
James W. Allen Dec. 1993 242 p
(AD-A277207) Avail: CASI HC A11/MF A03

Numerous studies have left little doubt that latent heat release (LHR) can significantly influence many features of extratropical cyclone systems. Recent experiments with the NCAR/PSU mesoscale model indicated that not only did different moisture parameterizations significantly affect model forecasts, but that forecasts for different cyclonic systems responded very differently to the parameterizations. Model output from the NCAR/PSU model is examined for two cyclonic systems, with four different parameterization experiments used to produce four forecasts for each system. The output was then examined in three and four dimensions to qualitatively and quantitatively determine the direct and indirect effects of latent heat release on model output. The results clearly showed the difference in the general dynamics of the two cyclones. One demonstrated a very strong reliance on diabatic processes for its early development, becoming more adiabatic late in its history, while the other initially developed very adiabatically and became more diabatic after about the mid-point of the forecast period. The cyclonic system that started out diabatically was more sensitive to moisture parameterization. The models clearly showed the differences between precipitation fields generated by the different parameterizations. In particular, allowing evaporation of precipitation in non-saturated layers greatly decreased the areal extent of light precipitation, while having minimal effect in areas of heavy precipitation. This report summarizes the activities undertaken by the US Army Mesomet Panel during the contract period. For the period to 31st March, 1993, nine interim reports were submitted and these contain full details of these activities. For the final period, 1st April - 31st December 1993, a more detailed account is provided here and includes, as Annex 2, the report of the Panel's final meeting in Munster, Germany, 9th-10th September, 1993. Its executive summary contains five important recommendations, all directed towards the future modeling activities at ARL. These arise from the lessons learned from the Mesomet Model Comparison Project undertaken during the contract period and subsequent Mesomet Workshop held in El Paso in June, 1992. Section 3 sets out what the Panel feels have been its achievements during the contract period, one in which considerable changes in policy direction occurred, some of which will have been influenced by the Panel's advice. Attention is drawn to the role of the Panel in involving the wider mesomet modeling community in ASL's activities, particularly through the Mesomet Model Comparison Project and El Paso Workshop. A major publication arising from these activities is a Mesometeorology Modeling monograph to be published by the American Meteorological Society in 1994. This is described in section 4. DTIC

This paper deals with high resolution numerical weather prediction experiments for the recent Bangladesh Tropical Cyclone (Apr. 1991). This devastating storm resulted in well over 100,000 deaths. The results from global model experiments carried out at a horizontal resolution of 213 waves (triangular truncation) and from a regional model at a horizontal resolution of 46 km are presented. Recent improvements in the model's parameterization of cumulus convection, land surface parameterization (the specification of ground wetness), and enhanced evaporation over low wind speed regions were included in the sensitivity studies. A PARAMETERIZATION OF CLOUD DROPLET NUCLEATION
S. J. Ghan, C. C. Chuang, and J. E. Penner Jan. 1994 7 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract DE-AC06-76RL-01830)
(DE94-007469; PNL-SA-23042; CONF-940115-31) Avail: CASI HC A02/MF A01

Droplet nucleation is a fundamental cloud process. The number of aerosols activated to form cloud droplets influences not only the number of aerosols scavenged by clouds but also the size of the cloud droplets. Cloud droplet size influences the cloud albedo and the conversion of cloud water to precipitation. Global aerosol models are presently being developed with the intention of coupling with global atmospheric circulation models to evaluate the influence of aerosols and aerosol-cloud interactions on climate. If these and other coupled models are to address issues of aerosol-interactions, the droplet nucleation process must be adequately represented. Ghan et al. have introduced a droplet nucleation parameterization for a single aerosol type that offers certain advantages over the popular Twomey parameterization. Here we describe the generalization of that parameterization to the case of multiple aerosol types, with estimation of aerosol mass as well as number activated. DOE

TROPICAL CYCLONE FORECASTERS REFERENCE GUIDE. 5: NUMERICAL TRACK FORECAST GUIDANCE Final Report
Richard A. Jeffries, Charles R. Sampson, Lester E. Carr, III, and Jan-Hwa Chu Dec. 1993 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277318; NRL/PU/7515-93-0011) Avail: CASI HC A03

One of the keys to safe and successful naval operations in the tropics is a thorough understanding of tropical meteorology. The Tropical Cyclone Forecasters Reference Guide is designed primarily as a ready reference for midlatitude forecasters required to provide tropical meteorology support to staff commanders. This report provides a comprehensive overview of numerical forecast guidance used to assess tropical cyclone motion and is chapter 5 of the reference guide. Subjects discussed include global and regional numerical modeling, major warning center operations, tropical cyclone numerical forecast aids, numerical modeling terminology, and applications of numerical forecast guidance to tropical cyclone forecasting.

AN INTEGRATED CLOUD OBSERVATION AND MODELING INVESTIGATION IN SUPPORT OF THE ARM PROGRAM
28 Jul. 1993 11 p
(Contract DE-FG02-90ER-61071)
(DE94-003160; DOE/ER-61071/3) Avail: CASI HC A03/MF A01

This annual technical progress report, based on the same four divisions used in our original proposal, provides only a brief synopsis of the research carried out during the past three years. We have also included a brief description of algorithms and computer programs that were transferred to the ARM management. Such transfers of knowledge and technique are vital for the success of the ARM program. Various members of our research group participated in two major field programs: the First ISSCP Regional Experiment (FIRE) Cirrus 2 Experiment held in Nov. 1991, in Kansas; and the Atlantic Stratocumulus Transition Experiment (ASTEX) held in the Azores in Jun. 1992. Although our participation in these campaigns was funded primarily through other agencies, the data collected in these programs were essential for certain components of our research. The graphical user interface programs that were transferred to ARM were a direct outgrowth of these field activities as well. In addition, we collected a variety of data at Penn State using our 94 GHz radar, microwave radiometer, wind profilers, and other instruments. Again these data were acquired to meet the needs of our proposed research.

USE OF CLOUD OBSERVATIONS AND MESOSCALE METEOROLOGY MODELS TO EVALUATE AND IMPROVE CLOUD PARAMETERIZATIONS
C. J. Walcek 30 Sep. 1993 5 p
(Contract DE-FG02-92ER-61364)
(DE94-003610; DOE/ER-61364/2) Avail: CASI HC A01/MF A01

This research program utilizes satellite and surface-derived cloud observations together with standard meteorological measurements to evaluate and improve our ability to accurately diagnose cloud coverage. Results of this research will be used to compliment existing or future parameterizations of cloud effects in general circulation models, since nearly all cloud parameterizations must specify a fractional area of cloud coverage when calculating radiative or dynamic cloud effects, and current parameterizations rely on rather crude cloud cover estimates. During the first phase of this research program, our goal is to evaluate and improve the methods for calculating cloud cover within a mesoscale meteorology model. To accomplish this, a mesoscale meteorology model will be quantitatively evaluated using available cloud cover databases including the U.S. Air Force 3DNEPH and RTNEPH satellite-derived cloud fields, as well as CART data as they become available. During the second phase of this research, the cloud cover data and improved parameterizations of cloud coverage developed during the first phase will be incorporated into a mesoscale meteorology model. Model forecasts which utilize the observed cloud coverage and depth should be improved relative to forecasts which crudely specify cloud properties.

WIND-SPEED MEASUREMENTS WITH A SCANNING ELASTIC-BACKSCATTER LIDAR
W. T. Buttler and W. E. Eichinger 1994 5 p Presented at the 21st American Meteorological Society Conference on Agricultural and Forest Meteorology, San Diego, CA, 7-10 Mar. 1994
(Contract W-7405-eng-36)
(DE94-004974; LA-UR-93-4526; CONF-940362-1) Avail: CASI HC A01/MF A01

During the 1992 Summer Olympics, the Los Alamos National Laboratory (LANL) lidar team participated in the Barcelona Air Quality Initiative (BAQI). One of the main objectives of this experiment was the remote measurement of wind speeds around the city to verify wind speeds and directions predicted by the Nonhydrostatic Mesoscale Model (MEMO). Remote determination of wind velocities in the mixing layer is important for the verification and determination of critical input parameters of urban-pollution transport models. Most present elastic-backscatter lidar wind speed measurement methods rely on data acquired over time periods between 5 to 10 minutes and 30 minutes to 1 hour. Lidar can measure the spatial properties of the wind field over large volumes of space. This capability is an improvement over present methods, which rely on instruments attached to balloons that measure only those winds along the path the balloon travels. The material that follows describes the principles implicit in the measurement of winds with an elastic-backscatter lidar, as well as the maximum cross-correlation algorithm used to extract wind speeds from lidar data acquired during the Summer Olympics at Barcelona, Spain, in July 1992.

(NASA-TM-109086; NAS 1.15:109086) Avail: CASI HC A03/MF A01

The Earth Radiation Budget Experiment (ERBE) instruments are designed

to measure the components of the radiative exchange between the Sun, Earth and space. ERBE is comprised of three spacecraft, each carrying a nearly identical set of radiometers: a three-channel narrow-field-of-view scanner, a two-channel wide-field-of-view (limb-to-limb) non-scanning radiometer, a two-channel medium field-of view (1000 km) non-scanning radiometer, and a solar monitor. Ground testing showed the scanners to be susceptible to self-generated and externally generated electromagnetic noise. This paper describes the pre-launch corrective measures taken and the post-launch corrections to the NOAA-9 scanner data. The NOAA-9 scanner has met the mission objectives in accuracy and precision, in part because of the pre-launch reductions of and post-launch data corrections for the electromagnetic noise. Author

Water vapor plays a fundamental role in weather and climate. It is the most important greenhouse gas and the most variable in space and time. The DOE Atmospheric Radiation Measurement program is devoting a large fraction of its resources for the accurate characterization of the column abundance and the distribution of water vapor with altitude. Balloon sondes, microwave radiometers, and Raman lidars are the major instruments either currently in use or under consideration for these tasks. Although the Multi-Filter Rotating Shadowband Radiometer (MFRSR) is primarily intended for use in accurate measurements of spectral short-wave radiation and in the measurement of spectral extinction by aerosol, it has the potential to measure total column water vapor as well. The authors report on a preliminary investigation of the MFRSR's capabilities with regard to accurate measurements of total column water vapor at times when there is a clear path to the sun, i.e., cloudless conditions. SIMULATION OF A PRECIPITATION EVENT IN THE WESTERN UNITED STATES
Jinwon Kim and S. T. Soong Sep. 1993 6 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-7405-eng-48)
(DE94-004835; UCRL-JC-114412; CONF-940115-23) Avail: CASI HC A02/MF A01

Wintertime precipitation is the major water resource in the western United States. Thus correct assessment of the wintertime precipitation is important in planning the summertime water supply and the development of future water resources. Precipitation forecast is also important for early warning of flooding. Regional precipitation depends chiefly on the large scale flow and local topography. Large scale moisture influx determines the amount of moisture available for the precipitation. Topography affects two major factors in the local precipitation: low-level vertical motion and local water vapor transport. Topography also affects partitioning the total precipitation into rain and snow since the snow line is usually lower than the peaks of major mountain ranges during wintertime. Modeling the features of regional precipitation has been intensely studied. Previous studies show that limited area models nested within large scale models or analysis can capture realistic features of storms. As limited area models usually have much finer spatial resolutions than large scale models, parameterized precipitation processes developed for large scale models may not be adequate for limited area models. We present a simulation of twelve-day precipitation over California from 11-23 Feb. 1986. We focus on features of precipitation such as the local distribution, total amount, and the occurrence of snowfall and rainfall. The simulation is carried out using a primitive-equation limited-area model. DOE

This research addresses the problem of moisture and temperature initializations in regional scale meteorological prediction models. Specifically, two approaches are used: one involving radar data and the second involving improved soil moisture content information. The model is initialized with rawinsonde data and then is forced to match convective signatures identified from WSR-57 radar data. Data from NOAA AVHRR radiometer data is used to initialize soil moisture information and generate large scale moisture fields. Methods of continuously updating soil moisture fields are under development. DTIC

PERFORMANCE OF A NEW WIND UPDATING SYSTEM FOR A PROGNOSTIC METEOROLOGICAL MODEL IN THE ENVIRONS OF MEXICO CITY
M. D. Williams 1993 31 p Presented at the IMP Workshop, Mexico City, Mexico, Dec. 1993
(Contract W-7405-eng-36)
(DE94-006243; LA-UR-94-229; CONF-931251-1) Avail: CASI HC A03/MF A01

Los Alamos National Laboratory and Institute Mexicano del Petroleo are completely a joint study of options for improving air quality in Mexico City. The US Department of Energy supported the efforts of the Los Alamos investigators, while PEMEX supported the efforts of the Mexican researchers. One of the first steps in the process was to develop an understanding of the existing air quality situation. In this context we have modified a three-dimensional, prognostic, higher order turbulence model for atmospheric circulation (HOTMAC) to treat domains which include an urbanized area. This sophisticated meteorological model is required because of the complexity of the terrain and the relative paucity of meteorological data. Mexico City lies at an elevation of approximately 7500 feet above sea level in a 'U' shaped basin which opens to the north. The city occupies a major part of the southwest portion of the basin. Upper level winds are provided by rawinsondes at the airport, while low-level winds are measured at several sites within the city. Many of the sites have obstructed upwind fetches for a variety of directions. During the wintertime when the worst air quality episodes occur, the winds are frequently light, and out of the northeast at lower levels, while above 1000 meters above the surface they are usually from the southwest. This means the winds are light within the city, but significant slope winds develop which influence the behavior of the pollutants. Frequently, the winds in the basin change as a seabreeze penetrates the basin from the northeast. The seabreeze produces a much different wind regime after its arrival in the late afternoon or early evening. This makes it important to update the winds in a realistic fashion. DOE

OPERATIONS SUMMARY FOR THE CONVECTION AND MOISTURE EXPERIMENT (CAMEX)
V. L. Griffin, A. R. Guillory, M. Susko, and J. E. Arnold Mar. 1994 188 p Original contains color illustrations
(NASA-TM-108445; NAS 1.15:108445) Avail: CASI HC A09/MF A02; 10 functional color pages

During the fall of 1993, NASA sponsored a field program called the Convection and Moisture Experiment (CAMEX) at Wallops Island, Virginia. CAMEX was a multidisciplinary experiment design to measure the three dimensional moisture fields over Wallops Island and to characterize the multifrequency radiometric signature of tropical convection over the Gulf Stream and southeastern Atlantic Ocean. This document summarizes the daily CAMEX activities, including ground and aircraft (NASA ER-2) operations, and includes 'quick-look' summaries of data acquisition along with data examples provided by the various CAMEX PI's. DROP SIZE DISTRIBUTIONS AND RELATED PROPERTIES OF FOG FOR FIVE LOCATIONS MEASURED FROM AIRCRAFT
J. Allen Zak Apr. 1994 131 p Sponsored in part by FAA, Atlantic City, NJ
(Contract NAS1-19341; RTOP 505-64-13-67)
(NASA-CR-4585; NAS 1.26:4585; DOT/FAA/CT-94/02) Avail: CASI HC A07/MF A02

Fog drop size distributions were collected from aircraft as part of the Synthetic Vision Technology Demonstration Program. Three west coast marine advection fogs, one frontal fog, and a radiation fog were sampled from the top of the cloud to the bottom as the aircraft descended on a 3-degree glideslope. Drop size versus altitude versus concentration are shown in three dimensional plots for each 10-meter altitude interval from 1-minute samples. Also shown are median volume radius and liquid water content. Advection fogs contained the largest drops with median volume radius of 5-8 micrometers, although the drop sizes in the radiation fog were also large just above the runway surface. Liquid water content increased with height, and the total number of drops generally increased with time. Multimodal variations in number density and particle size were noted in most samples where there was a peak concentration of small drops (2-5 micrometers) at low altitudes, midaltitude peak of drops 5-11 micrometers, and high-altitude peak of the larger drops (11-15 micrometers and above). These observations are compared with others and corroborate previous results in fog gross properties, although there is considerable variation with time and altitude even in the same type of fog. FORECASTERS HANDBOOK FOR THE PHILIPPINE ISLANDS AND SURROUNDING WATERS Final Report
Forrest R. Williams, Glenn H. Jung, and Ronald E. Englebretson Dec. 1993 357 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277993; NRL/PU/7541-92-0001) Avail: CASI HC A16

The analysis and forecasting of atmospheric and oceanic conditions important to air/ sea operations in the Philippine Islands area are described. The area covered includes the islands -- Luzon the Visayas (the central islands) and Mindanao -- from about 4.7 deg N to 21.5 N and 117 E to 127 E; and the Philippine Sea, Luzon Strait, South China Sea, and Sulu Sea. Seasonal climatologies of the southwest and northeast monsoons and tradewind regime, plus electromagnetic and ducting conditions, are presented. Appendices provide additional climatologies, a study of tropical cyclone characteristics, climatic normals for 60 Philippine stations, and percent frequencies of wave heights. Five case studies examine current accuracy of the Navy Operational Global Atmospheric Prediction System (NOGAPS) model analyses and prognoses. Tropical cyclone bulletins issued by the Joint Typhoon Warning Center, Guam, are identified and described; forecast philosophies are discussed. Interaction of Typhoon Yunya and the eruption of Mount Pinatubo volcano in June 1991 is described, and the dangers posed to aviation by volcanic ash are discussed. DTIC

TRMM-RELATED RESEARCH: TROPICAL RAINFALL AND ENERGY ANALYSIS EXPERIMENT Final Report
Verner E. Suomi, S. Ackerman, B. Hinton, and D. Martin May 1994 11 p Original contains color illustrations
(Grant NAG5-1586)
(NASA-CR-195834; NAS 1.26:195834) Avail: CASI HC A03/MF A01; 1 functional color page

The overall science objective of the participation in TRMM is the determination of daily rainfall and latent heating in the tropical atmosphere using TRMM and complementary spacecraft observations. The major focus these first three years has been to extend, in space and time, the TRMM satellite observations of rainfall. Observations from TRMM active and passive microwave radiometers will provide the fundamental observations for understanding the hydrological cycle of the tropics. Due to the orbit of the TRMM satellite and the extreme variability of convective rain systems, the TRMM observations provide rainfall estimates representative of a one month period. Monthly mean rainfall rates provide valuable information; however, this time scale limitation neglects the great value of the data towards a better understanding of the physics of tropical convection. Many tropical periodicities will not be characterized by these monthly averages, e.g. diurnal cycles, the 4-6 day easterly waves, and the 30 to 60 day cycle. In the spatial domain, due to its orbit, the TRMM satellite will over-fly many convective systems only once. Indeed, some precipitating systems will not be sampled at all. Observations from geostationary satellites can be used to extend the TRMM observations to smaller time and space scales. Although geostationary satellites cannot probe the interiors of precipitating systems, they do observe their life cycles. To acquire information on cloud water content and rain rate, it is proposed to combine geostationary and other satellite observations with the TRMM satellite measurements.

OCEAN ACOUSTIC PROPAGATION MEASUREMENTS AND WAVE PROPAGATION IN RANDOM MEDIA
Terry E. Ewart and Stephen A. Reynolds Apr. 1993 24 p
(Contract N00014-90-J-1260)
(AD-A276165) Avail: CASI HC A03/MF A01

Over the last two decades, observations of acoustic scintillations in the ocean have been useful in testing theories that predict the statistics for wave propagation in random media (WPRM). Ocean acoustic observations differ from scattering processes observed in other WPRM sub-fields in two important ways. First, the statistics of the refractive index can be determined accurately from oceanographic measurements. Hence, exacting tests of theories can be done when careful measurements of the medium and the wavefield are made synoptically. Second, the scattering of acoustic energy is predominantly influenced by the ocean internal wave field, which tends to exhibit statistical stationarity in many ocean regimes, and not by non-stationary turbulent processes, as observed in the atmosphere. We discuss space/time acoustic propagation experiments carried out in three scattering regimes: (1) weak, where the Rytov approximation is valid; (2) moderate, where multiple scattering theory is required; and (3) the case where multiple scattering in a single medium irregularity is encountered. A review is presented of the measurements and comparisons with theory. It is clear from field and numerical experiments that 2-point statistics cannot possibly explain the observations of intensity. Because two-point statistics are the norm when interpreting both medium and wavefield measurements, the possible failure of Gaussian statistics must be addressed. This has yet to be done. We will discuss remaining issues for which we believe further study is needed. DTIC

ADCIRC: AN ADVANCED THREE-DIMENSIONAL CIRCULATION MODEL FOR SHELVES, COASTS, AND ESTUARIES. USER'S MANUAL FOR ADCIRC-2DDI Technical Report No. 2
J. J. Westerink, R. A. Luettich, Jr., C. A. Blain, and Norman W. Scheffner Jan. 1994 168 p
(AD-A276150; WES/TR/DRP-92-6-2) Avail: CASI HC A08/MF A02

This report describes the use of model ADCIRC-2DDI, a two-dimensional, depth-integrated, finite-element-based hydrodynamic circulation code. ADCIRC-2DDI solves the shallow-water equations in their full nonlinear form and can be forced with elevation boundary conditions, zero normal boundary fluxes, variable spatial and temporal free surface stress and atmospheric pressure forcing functions in addition to Coriolis and tidal potential forcing terms. The algorithms that comprise ADCIRC-2DDI allow for extremely flexible spatial discretizations, which results in a highly effective minimization of the discrete size of any problem. Furthermore, these algorithms show good stability characteristics, generate no spurious artificial modes, have no inherent artificial damping, and are extremely efficient. The resulting model can be applied to computational domains ranging from the deep ocean to estuaries. Furthermore, the model is able to efficiently run months to years of simulation while providing detailed intra-tidal response characteristics. A complete description of all user aspects is

given in this document, including code setup and a description of all input and output files. Both model-specific and general modeling practices are discussed. Finally, two examples are presented. Sample input and output files for these examples are included in Appendices A and B. DTIC

THE EFFECT OF WESTERLY WIND BURSTS ON A TROPICAL OCEAN GENERAL CIRCULATION MODEL M.S. Thesis
Charles A. Weddle Dec. 1993 141 p
(AD-A276423) Avail: CASI HC A07/MF A02

A primitive equation general circulation model with imbedded mixed layer physics has been used to investigate the response of the equatorial Pacific ocean to daily varying winds and westerly wind bursts. The major issue addressed by this study is the impact of daily varying winds, including westerly wind bursts, in the modeling of the tropical Pacific ocean and El Nino. In the developmental phase, the sensitivity of the model to the integration time step and the domain size were investigated. The results of this work were used to determine the optimal time step and model domain size for the main experimental model runs. In the experimental phase, the model was spun-up using time averaged wind stresses. The model ocean was then exposed to two years of realistic daily varying wind stresses covering the period of 1991 and 1992. The model developed an El Nino like response that corresponded in several respects with observed features of the 1991-92 El Nino. The model also developed tropical instability waves in the eastern Pacific similar to those observed in situ and in satellite SST images. The model's responses to the tropical cyclones that occurred during 1991-92 were also consistent in several ways with observations. DTIC

SURFACE FORWARD-SCATTERED ACOUSTIC MEASUREMENTS AND ANALYSIS Final Report
E. J. Yoerger, M. Wilson, and S. T. McDaniel Jun. 1993 5 p
(AD-A276998; NRL/PP/7174-93-0034) Avail: CASI HC A01/MF A01

A shallow water, high-frequency acoustic experiment was conducted off the coast of Panama City Florida during August 1991. Acoustic measurements of surface forward scattering, surface reverberation, and direct path intensities were made utilizing two large stationary towers resting on the seafloor. Each tower was equipped with horizontal and vertical receiving arrays, while the two sources were located on only one of the towers. The water bottom was 30 m deep and covered with a fine, rippled sand. The range of acoustic frequencies varied from 20 kHz to l8O kHz. Concurrent environmental measurements including wave heights, sound velocity profiles, and sample cores were made. This paper reports on the surface forward-scattered measurements made at 24 kHz. AIR-SEA INTERACTION PATTERNS IN THE EQUATORIAL PACIFIC M.S. Thesis
John E. Kent Dec. 1993 194 p
(AD-A277305) Avail: CASI HC A09/MF A03

We have investigated air-sea interaction patterns in the equatorial Pacific during the 1991-1992 El Nino/Southern Oscillation (ENSO) event. Our study focused on the identification of spatial and temporal relationships between sea surface temperatures, subsurface temperatures, and winds. These relationships were examined using time series and statistical analyses of atmosphere and ocean data from the moored buoys of the Tropical Oceans-Global Atmosphere (TOGA) program. Our results strongly suggest that the heat content of the ocean mixed layer greatly affected air-sea interactions. In almost all regions, mixed layer warming was followed within one week by increased winds. In most cases, the mixed layer warming before wind events was accompanied by a thickening of the mixed layer, suggesting that internal waves were strongly influencing air-sea interactions. Increased winds tended to precede surface cooling and subsurface warming by a few days. There were strong correlations between warming (cooling) thermocline temperature and increased (decreased) zonal winds at the central and eastern equatorial Pacific buoys. In the central Pacific, thermocline warming (cooling) was associated with westerlies (easterlies). This suggested that equatorially trapped Kelvin waves warmed and thickened the mixed layer, resulting in increased zonal winds. In the central Pacific, these local zonal winds then reinforced the Kelvin waves through downwelling and upwelling. Ocean temperature inversions were found throughout the Pacific. DTIC

PREDICTION OF THE PLANE WAVE BEAMFORMED ACOUSTIC ARRIVAL STRUCTURE FOR THE 1992 BARENTS SEA COASTAL TOMOGRAPHY TEST
John L. Mykyta Dec. 1993 46 p
(AD-A276741) Avail: CASI HC A03/MF A01

In an effort to solve the forward propagation problem associated with the 1992 Barents Sea Polar Front Experiment Tomography Test, the transmission of a 224 Hz pulse signal from a near bottom sound source to a vertical hydrophone array was simulated based on three-dimensional ray theory. Through numerical raytracing, followed by eigenray searches and estimations of ray amplitudes, searches and estimations of ray amplitudes, phases and travel times, the arrival structure as a function of time and elevation angle was constructed. The simulation was performed for both a two-dimensional and three-dimensional modeled ocean environment in order to examine the significance of three-dimensional effects. The predicted arrival structures compare well with the observed data. Three-dimensional effects proved to be significant only for the latest arrivals. DTIC

THREE DIMENSIONAL VORTICITY FIELD IN THE CALIFORNIA CURRENT SYSTEM M.S. Thesis
Gonzalo Montenegro Mar. 1993 110 p
(AD-A276951) Avail: CASI HC A06/MF A02

Hydrographic data has traditionally been used only to determine dynamical features, specifically dynamic topography and geostrophic currents relative to an assumed level of no motion. However, the assumption of geostrophic balance has been questioned because of the neglect of ageostrophic effects. Measuring vorticity and vertical motion has always been technically demanding and costly. Due to the importance of these parameters new techniques have been developed, among them a diagnostic technique known as the C-vector Method, which uses the wind stress and the geostrophic balance as forcing functions to infer these quantities. Using this technique, the three dimensional vorticity field was computed for the California current system during the Coastal Transition Zone (CTZ) program. Hydrographic (CTD) and wind data sets were used assuming a quasi-geostrophic system. Also computed was vertical vorticity of the C-vector, known as the Psi function, which has a direct relationship with the vertical velocity, making it possible to infer upward or downward motion in coastal waters. A satisfying correlation was found between surface temperature fields, satellite imagery, and vertical motions inferred from the Psi function. The C-vector has therefore been shown to be a very reliable method of diagnosing vorticity and vertical circulation. DTIC

VALIDATION SUPPORT OF THE ERIM OCEAN MODEL Technical Report, 4 Feb. 1993 - 3 Feb. 1994
M. A. True 28 Feb. 1994 36 p
(Contract N00014-93-C-2019)
(AD-A277364; ERIM-251600-4-F) Avail: CASI HC A03/MF A01

The ERIM Ocean Model (EOM) is a comprehensive program for the simulation of SAR images of the ocean surface. EOM was delivered to NRL and integrated into the NASE Modeling System in 1991. The purpose of the NASE-EOM module is to simulate ocean surface effects as seen by SAR sensors. The purpose of the validation phase of the NASE-EOM project was to determine which of EOM's physics are reliable and which physics need improvement. To that end, a series of validation tests were run using NASE-EOM. For the code-to-theory test, the action spectral

density equation was solved in EOM and compared with the linear solution. The results showed some numerical diffusion in EOM's solution which were reduced with finer spectral grid spacing. The code-to-code comparison consisted of a series of feature tables. The final validation test was the code-to-data comparison. The 11 test cases were run on the NASE Modeling System at NRL and the simulations were compared to experimental data. The simulated SAR signals were similar to each other and to the data for most test case, but the simulated clutter had different appearances in the SAR codes due to differences in the simulation of the propagation of the waves during the SAR imaging time, the averaging to reduce the speckle, and the angular dependence of the equilibrium wave height spectrum. PROFILING ALACE INSTRUMENTS Final Report, 1 Apr. 1989 - 31 Mar. 1992
Jeff Sherman 20 Mar. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-C-6014)
(AD-A277246; NRL-CR/7330-93-0001) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The autonomous Lagrangian circulation explorer (ALACE) is a free drifting oceanographic float which drifts at a level of neutral buoyancy and periodically rises to the surface where it transmits data to System Argos satellites and is located by them. The basic float was intended to observe ocean currents but recent developments, described in this report, have led to three new versions with expanded capabilities. One model reports temperature profiles from each ascent cycle. A second reports profiles of both temperature and conductivity from which sound speed profiles can be calculated. A third instrument observes microtemperature profiles on repeated vertical profiles and records them internally. At the end of its mission this float must be located from its Argos signals and recovered. All three floats have been field tested and their performances are discussed. The sound speed profiles obtained from the first conductivity and temperature measurements are accurate to 0.25 m/s after correcting for instrument drift using relatively stable climatological temperature versus salinity relations at depth. Subsequent sensor improvements are believed to have reduced drift. DTIC

ESTIMATING SUBPYCNOCLINE DENSITY FLUCTUATIONS IN THE CALIFORNIA CURRENT REGION FROM UPPER OCEAN OBSERVATIONS
Robert L. Haney, Robert A. Hale, and Curtis A. Collins Feb. 1994 75 p
(AD-A277278; NPS-MR-94-001) Avail: CASI HC A04/MF A01

A method for extending upper ocean density observations to the deep ocean is tested using a large number of deep CTD stations in the California current. The specific problem considered is that of constructing the best estimate for the density profile below a certain depth, D, given an observed profile above that depth. For this purpose, the estimated disturbance profile is modeled as a weighted sum of empirical vertical modes (empirical orthogonal functions, EOF's). The EOF's were computed from the surface to 2000 m using 126 largely independent CTD stations off Pt. Sur, California. Separate computations were made for the summer half-year (mid-April to mid-October) and the winter half-year (mid-October to mid-April). For each observed density profile, the EOF weights that determine the estimated profile were obtained by performing a successive least squares fit of the disturbance density profile above D to the first N EOF's. In this study, N was taken to be 7, which is the number of EOF's considered necessary to account for the 'signal' in the profiles. The estimated profiles were then verified against the observed profiles to 2000 m, and the results are presented as a function of the depth D. DTIC

ENSO FORCED VARIATIONS OF THE SEA SURFACE TEMPERATURE AND ADJUSTED SEA LEVEL ALONG THE WEST COAST OF THE UNITED STATES M.S. Thesis
John B. Skillman Dec. 1993 98 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277306) Avail: CASI HC A05

Daily coastal surface temperature and adjusted sea level data for the period 1955-1988 were used to characterize the surface temperature and adjusted sea level anomalies and the propagation of features along the west coast of the United States during El Nino-southern oscillation (ENSO). The strong ENSO years examined were 1957-58, 1972-73, and 1982-83. Moderate ENSO years used were 1966, 1976, and 1987. To look at regional differences in the signals, the time series of daily coastal surface temperature and adjusted sea level were divided into three distinct regions: the southern region (i.e., Southern California), the central upwelling region (i.e., Central California), and the northern region (i.e., Northern California, Oregon, and Washington). The anomaly series were compared with cross-spectral analysis. Phase speeds and wavenumbers were estimated from the difference in phase between La Jolla and the other stations as a function of frequency band. These were used to characterize the structure of waves associated with the propagation of the positive surface temperature and adjusted sea level anomalies. These wave characteristics were found to be consistent with coastally trapped internal Kelvin waves, due to their phase speed, wavelength, and nondispersive nature. Phase speeds for frequencies corresponding to 4-20 day periods were 60-100 km/day, based on temperature and sea level. A regression of wavenumber against frequency gives phase speeds of about 65-85 km/day that are consistent with Kelvin wave theory for typical west coast ocean structure and bathymetry. DTIC

LONG TRANSECT SEAFLOOR SEISMIC ARRAY: A COMPONENT OF SAMSON (SOURCES OF AMBIENT MICRO SEISMIC OCEAN IC NOISE) Final Report, 1 Nov. 1989 - 30 Sep. 1993
Spahr C. Webb Jan. 1994 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1088)
(AD-A277009; MPL-U-10/94) Avail: CASI HC A02

During the SAMSON experiment, an array of at least twelve seafloor instruments was deployed to measure ambient seismo-acoustic noise. SAMSON is a large, coordinated experiment featuring several land and seafloor seismic arrays directed at studying the generation and propagation of very low frequency (1 mHz to 1 Hz) ambient noise. Surface waves were measured at the coast by the FRF array (established by NCEL), by a pressure array near the coast, and in deep water with wave buoys which are part of the ONR funded SWADE program. The seismic array extended from shallow into deep water from the North Carolina coast. Data from the array was incoherently processed and principally used to study the evolution of the seafloor noise field as a function of distance from the coast and with depth. The array also serves to tie together measurements made by the three coherent arrays: the first on land, the second in the shallow water very near the coast, and the third in deep water beyond the shelf. Some instruments of the incoherent array were elements of the two marine coherent arrays. DTIC

The broad goal of this research is to address the problem of understanding the propagation of light in the ocean and its ramifications for underwater imaging. In particular, we are interested in developing inversion algorithms for determining the total absorption and scattering coefficients and the small angle values of the volume scattering function from simple optical experiments such as the propagation of collimated light beams over distances of several total attenuation lengths. This is particularly important in understanding the limitations of current computer models which predict the propagation of light underwater. DTIC

(DE94-008670; UCRL-ID-115329; PCMDI-14) Avail: CASI HC A04

Recent investigations have considered whether it is possible to achieve early detection of greenhouse-gas-induced climate change by observing changes in ocean variables. In this study, we use model data to assess some of the uncertainties involved in estimating when we could expect to detect ocean greenhouse warming signals. We distinguish between detection periods and detection times. As defined here, detection period is the length of a climate time series which must be available in order to detect a given linear trend in the presence of the natural climate variability. Detection period is defined in model years and is independent of reference time and the real time evolution of the signal. Detection time is computed for an actual time-evolving signal from a greenhouse warming experiment and depends on the experiment's start date. Two sources of uncertainty are considered - those associated with the level of natural variability or noise, and those associated with the time-evolving signals. We analyze the ocean signal and noise for spatially-averaged ocean circulation indices such as ice volume, heat and fresh water fluxes, rate of deep water formation, salinity, temperature, and transport of mass. The signals for these quantities are taken from recent time-dependent greenhouse warming experiments performed by the Hamburg group with a coupled ocean-atmosphere general circulation model. The natural variability noise is derived from a 300-year control run performed with the same coupled atmosphere-ocean model and from two long (greater than 3,000 year) stochastic forcing experiments in which an uncoupled ocean model was forced by white noise surface flux variations. In the first experiment the stochastic forcing was restricted to the fresh water fluxes, while in the second experiment the ocean model was additionally forced by variations in wind stress and heat fluxes. The mean states and ocean variability are very different in the three natural variability integrations. DOE

BIOLUMINESCENCE BATHYPHOTOMETER Patent
Kenneth M. Ferer, inventor (to Navy), James F. Case, inventor (to Navy), Edith A. Widder, inventor (to Navy), Steven A. Bernstein, inventor (to Navy), and Mark Lowenstine, inventor (to Navy) 23 Nov. 1993 17 p Filed 8 Jul. 1992
(AD-D016102; US-Patent-5,264,906; US-Patent-Appl-SN-910378; US-Patent-Class-356-28) Avail: US Patent and Trademark Office

A high intake, defined excitation, vertical Profiling survey, bioluminescence bathyphotometer system is discussed. The system was designed to measure, from a statistically significant sample with a calibrated hydromechanical stimulus, the following: (1) the bioluminescence of phytoplankton and zooplankton organisms in the oceanic water column to depths of 400 meters in absolute units of photons per second per volume (intensity) or photons per volume (total flux); (2) the concentration of bioluminescent population in flashes per volume; (3) the average light intensity per bioluminescent event; and (4) population flash dynamics. LIGHT IN THERMAL ENVIRONMENTS (LITE) WORKSHOP Final Technical Report, 1993
1993 59 p Workshop held in Woods Hole, MA, 10-12 Jan. 1993 Sponsored in part by NSF and RIDGE
(Grant NAGw-3452)
(NASA-CR-195851; NAS 1.26:195851) Avail: CASI HC A04/MF A01

Light emitted from high temperature black smokers (350 C) at mid-ocean ridge spreading centers has been documented, but the source of this light and its photochemical and biological consequences have yet to be investigated. Preliminary studies indicate that thermal radiation alone might account for the 'glow' and that a novel photoreceptor in shrimp colonizing black smoker chimneys may detect this 'glow.' A more controversial question is whether there may be sufficient photon flux of appropriate wavelengths to support geothermally-driven photosynthesis (GDP) by microorganisms. Although only a very low level of visible and near infrared light may be emitted from any single hydrothermal vent, several aspects of the light make it of more than enigmatic interest. First, the light is clearly linked to geophysical (and perhaps geochemical) processes; its attributes may serve as powerful index parameters for monitoring change in these processes. Second, while the glow at a vent orifice is a very local phenomenon, more expansive subsurface environments may be illuminated, thereby increasing the spatial scale at which biological consequences of this light might be considered. Third, in contrast to intermittent bioluminescent light sources in the deep sea, the light emitted at vents almost certainly glows or flickers continuously over the life of the individual black smokers (years to decades); collectively, light emitted from black smokers along the ocean's spreading centers superimposed on background Cerenkov radiation negates the concept of the deep sea as an environment devoid of abiotic light. Finally, the history of hydrothermal activity predates the origin of life; light in the deep sea has been a continuous phenomenon on a geological time scale and may have served either as a seed or refugium for the evolution of biological photochemical reactions or adaptations. EVOLUTION OF UPWELLING FRONTS OFF THE COAST OF PORTUGAL Final Technical Report
8 May 1994 44 p
(Grant NAGw-2058)
(NASA-CR-195692; NAS 1.26:195692) Avail: CASI HC A03/MF A01

We have analyzed the spatial and temporal variability of chlorophyll in the Atlantic Ocean off the Portugal coast using satellite imagery from 1979 to 1986 in conjunction with wind data. The spatial patterns in the imagery show the typical inshore-offshore and east-west gradients, while the temporal patterns show seasonal high winter values and low summer values. In the satellite imagery for the period 1979-1986, stable mesoscale and large scale patterns recurred despite interannual differences in absolute satellite-derived pigment concentrations. EVOLUTION OF DIURNAL SURFACE WINDS AND SURFACE CURRENTS FOR MONTEREY BAY M.S. Thesis
Michael D. Foster Dec. 1993 97 p
(AD-A277649) Avail: CASI HC A05/MF A02

The diurnal-period fluctuations of winds and surface currents are analyzed for Sep. 1992 in and around Monterey Bay. Wind records are compared for three coastal stations and two mooring sites. Remotely-sensed surface current observations from two CODAR (HF radar) sites are used to explore the ocean's response to diurnal-period forcing. An average diurnal cycle is formed at each wind station and at all CODAR bins. The earliest sea breeze response is seen at the coastal wind stations where morning winds accelerate toward the coastal mountain ranges. A few hours later, the coastal winds accelerate to the southeast down the Salinas Valley. Offshore afternoon winds rotate from their normal alongshore orientation to also become aligned with the valley. The CODAR-derived surface currents respond in less than the two-hour sampling rate to the onset of the diurnal onshore winds. Currents accelerate in the direction of the Salinas Valley. As the day progresses, the more offshore currents rotate clockwise out from under the winds in a possible Ekman or inertial adjustment that continues throughout the night and spreads onshore. In the afternoon, a complicated eddy pattern develops near shore in a possible response to the coastal boundary. DTIC

INDEX AND BULK PARAMETERS FOR FREQUENCY-DIRECTION SPECTRA MEASURED AT CERC FIELD RESEARCH FACILITY Final Report, Sep. 1989 - Aug. 1990
Charles E. Long and Wendy L. Smith Mar. 1994 86 p
(AD-A277759; CERC-94-2) Avail: CASI HC A05/MF A01

A multiyear series of wind wave frequency-direction spectral measurements has been undertaken at the Field Research Facility of the Coastal Engineering Research Center, U.S. Army Engineer Waterways Experiment Station. Cross-spectra of surface-corrected signals from a linear array of nine bottom-mounted pressure sensors have been used in conjunction with an iterative maximum likelihood algorithm to estimate frequency-direction spectra in about 8 m of water, approximately 900 M offshore. This report provides an index of and describes a means of access to 1,505 spectral observations obtained from September 1989 to August 1990. This period represents the fourth year of data collection. In addition to a list of data collection start times, a set of bulk parameters are provided to characterize the observations. Included are characteristic wave height, spectral peak frequency and corresponding peak period, peak wave direction, and directional spread. Time series graphs of these parameters, as well as local winds and currents, illustrate some of the salient climatology. DTIC

FINE AND MICROSTRUCTURE OBSERVATIONS AT FIEBERLIN G GUYOT R/V NEW HORIZON CRUISE REPORT
Ellyn T. Montgomery and John M. Toole Nov. 1993 33 p
(Contract N00014-89-J-1073)
(AD-A277917; WHOI-93-51) Avail: CASI HC A03/MF A01

This report describes fine structure and microstructure profile data taken on a cruise to Fieberling Guyot, a seamount in the northeast subtropical Pacific Ocean. The work performed at sea, instruments used, data return and processing procedures are summarized. This cruise took place between March 4 and March 28, 1991 on the R/V New Horizon, and was part of the interdisciplinary Accelerated Research Initiative (ARI) for Abrupt Topography sponsored by the Office of Naval Research. An overall goal of the ARI was to understand the physical, biological, and geological processes occurring near a seamount. The scientific objective of the Seamount Mixing Cruise was to collect data describing the oceanic fine-scale velocity and density fields, as well as the related turbulence and mixing in the vicinity of the seamount. The High Resolution Profiler (HRP) was deployed 95 times above and around the seamount. As well, two test dives were conducted on the way to the site, and eight deployments completed in deep basins off the southern California coast before returning to port. Three near-synoptic surveys of the seamount were completed with the deployment of 128 Expendable Current Profilers (XCP's). The temperature field of the upper 760 meters of water within a 50 kilometer radius of the seamount was mapped using 144 Expendable Bathythermographs (XBT's). DTIC

FLUID MECHANICAL MEASUREMENTS WITHIN THE BOTTOM BOUNDARY LAYER OVER THE NORTHERN CALIFORNIA CONTINENTAL SHELF DURING STRESS
J. J. Fredericks, John H. Trowbridge, A. J. Williams, III, Steven J. Lintz, and Bradford Butman Sep. 1993 110 p
(Contracts N00014-89-J-1067; N00014-89-J-1058)
(AD-A277916; WHOI-93-32) Avail: CASI HC A06/MF A02

In studying the processes controlling particle distribution of fine sediments over the continental shelf, the height, structure and dynamics of the bottom boundary layer must be better understood. The Sediment Transport Events on Shelves and Slopes (STRESS) program provides a comprehensive set of data over the bottom half of the water column at the 90 m and the 130 m isobaths along the northern California continental shelf during the winters of 1988-89 and 1990-91. This report presents the STRESS salinity, temperature, velocity, wave characteristics and attenuation data. The report describes the processing, provides plots and tables of the data and corresponding statistics for evaluation of the data, and documents the data files. The combined set of moored and tripod mounted instrument measurements provides integrated, hourly-averaged profiles of the lower half of the water column at the four sites which can be used for analysis and modeling purposes. SEASOAR AND CTD OBSERVATIONS DURING A COARE SURVEYS CRUISE, W9211C, 22 JANUARY - 22 FEBRUARY, 1993
A. Huyer, P. M. Kosro, R. OMalley, and J. Fleischbein Oct. 1993 328 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A277925) Avail: CASI HC A15

An international Coupled Ocean-Atmosphere Response Experiment (COARE) was conducted in the warm-pool region of the western equatorial Pacific Ocean over a four-month period from November 1992 through February 1993. Most of the oceanographic and meteorological observations were concentrated in the Intensive Flux Array (IFA) centered at 1 deg 45 min S, 156 deg 0 min E. As part of this experiment, the R/V Wecoma conducted three survey cruises on the R/V Wecoma; each cruise included measurements of the temperature, salinity and velocity distribution in the upper 300 m of the ocean, and continuous meteorological measurements of wind, air temperature, humidity, etc. Most of these measurements were along a butterfly pattern that was sampled repeatedly during the three COARE Surveys cruises, W9211A and W911B, and W9211C. This report summarizes the Seasoar and CTD observations from Wecoma's third COARE Surveys cruise, W9211C. It also provides a cruise narrative, and a brief description of the data processing procedures. Derived from text

This report describes fine structure and microstructure profile data taken on R/V Oceanus cruise 250 leg 4, between March 25 and April 24, 1992. During this cruise, an area of the Canary Basin near the Subduction Experiment's central mooring was surveyed with the High Resolution Profiler (HRP). The goals of the survey were to describe the hydrographic properties of the water adequately to recommend a location for the North Atlantic Tracer Release Experiment (NATRE) tracer injection, and to characterize the microstructure for comparison with the NATRE results. The work performed at sea, instrumentation, data return and processing procedures will be summarized in this report. DTIC

The format of the symposium adopted for the past few years was followed again this year with a compact eight-day schedule with an integrated program of biology, quantum chemistry, and condensed matter physics. The topics of the sessions covered by these proceedings include Modeling of Biomolecules and Intramembranal Systems, Protein-DNA Interactions, Electron Transport Mechanisms in Biological Systems, and Computational Approaches to Molecular Design. The articles have been subjected to the ordinary refereeing procedures of the International Journal of Quantum Chemistry. The articles presented in the sessions on quantum chemistry, condensed matter physics, and associated poster sessions are published in a separate volume of the International Journal of Quantum Chemistry. SPECTRAL INHOMOGENEITY OF THE BACTERIAL LIGHT-HARVESTING ANTENNAE: CAUSES AND CONSEQUENCES Ph.D. Thesis
Frank vanMourik 1993 125 p Sponsored in part by Netherlands Organization for Scientific Research, and United Kingdom Science and Engineering Research Council
(Grant EEC-SC1-0004-C)
(ETN-94-96020) Avail: CASI HC A06/MF A02

A general introduction to bacterial photosynthesis, light harvesting, the importance of exciton interaction, exciton theory, the disordered dimer, and larger aggregates (LH-1), is presented. The following studies are then reported: exciton interactions in the light harvesting antenna of photosynthetic bacteria studied with triplet singlet spectroscopy and singlet triplet annihilation on the B820 subunit form of Rhodospirillum rubrum; spectroscopic characterization of the low light B800-850 light harvesting complex of Rhodopseudomonas palustris, strain 2.1.6; self assembly of the LH-1 light harvesting antenna of Rhodospirillum rubrum, a time-resolved study of the aggregation of the B820 subunit; excitation transfer dynamics and spectroscopic properties of the light harvesting BChl a complex of Prosthecochloris aestuarii; spectral inhomogeneity of the light harvesting antenna of Rhodospirillum rubrum probed by T-S spectroscopy and singlet

triplet annihilation at low temperatures; and energy transfer and aggregate size effects in the inhomogeneously broadened core light harvesting complex of Rhodobacter sphaeroides. ESA

ON THE RECIPROCAL RELATIONSHIP BETWEEN LIFE HISTORIES AND POPULATION DYNAMICS
Odo Diekmann (Leiden Univ., Netherlands.) and J. A. J. Metz (Leiden Univ., Netherlands.) May 1993 16 p Submitted for publication Sponsored by Netherlands Organization for Applied Scientific Research TMO Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0924-2953)
(CWI-AM-R9302; ETN-94-96166) Copyright Avail: Issuing Activity (European Space Agency (ESA))

A possible mathematical framework for dealing with the following reciprocal questions is presented: how life history mechanisms shape the size and structure of populations; and how past population dynamics may have molded present day life histories. This framework is thought to be more general than comparable frameworks presented in the past; still sufficiently well specified to allow a directed search for both general theorems and tractable special cases; and still considerably less encompassing than one would wish. Within that framework, possible technical approaches to the questions above are discussed. Speculations about possible extensions to larger biological contexts are made in conclusion. ESA

TOWARDS A DETAILED UNDERSTANDING OF THE STRUCTURAL VARIABILITY IN LIGNINS: A NEW APPROACH
N. G. Lewis and G. H. N. Towers 1993 16 p
(Contract DE-FG06-91ER-20022)
(DE94-007449; DOE/ER-20022/T1) Avail: CASI HC A03/MF A01

This reporting period witnessed a number of exciting and important breakthroughs in the study of lignin synthesis in plants and resulted in a significant deviation from the work plan originally proposed. Taken together, the authors' results reveal an emerging picture of a highly ordered assembly of the lignin polymer at the plasma membrane/cell-wall interface, in contrast to original considerations projecting a random series of coupling reactions. The Progress Report is divided into two sections: the first section reflects the interlocking research completed to date in the laboratories of N.G. Lewis and G.H.N. Towers. In the broadest sense, the Lewis group has focused mainly on woody plants, whereas the Towers laboratory examined similar processes in cereals/grasses. The second section compiles published work, a summary of manuscripts in preparation, and work currently underway for year three of the existing grant. DOE

A GENETIC ALGORITHM BASED METHOD FOR DOCKING FLEXIBLE MOLECULES
R. S. Judson, E. P. Jaeger, and A. M. Treasurywala Nov. 1993 38 p
(Contract DE-AC04-76DR-00789)
(DE94-007525; SAND-93-8688) Avail: CASI HC A03/MF A01

The authors describe a computational method for docking flexible molecules into protein binding sites. The method uses a genetic algorithm (GA) to search the combined conformation/orientation space of the molecule to find low energy conformation. Several techniques are described that increase the efficiency of the basic search method. These include the use of several interacting GA subpopulations or niches; the use of a growing algorithm that initially docks only a small part of the molecule; and the use of gradient minimization during the search. To illustrate the method, they dock Cbz-GlyP-Leu-Leu (ZGLL) into thermolysin. This system was chosen because a well refined crystal structure is available and because another docking method had previously been tested on this system. Their method is able to find conformations that lie physically close to and in some cases lower in energy than the crystal conformation in reasonable periods of time on readily available hardware. DEVELOPMENT AND APPLICATION OF PHOTOSENSITIVE DEVICE SYSTEMS TO STUDIES OF BIOLOGICAL AND ORGANIC MATERIALS
S. M. Gruner and G. T. Reynolds 14 Sep. 1993 11 p
(Contract DE-FG02-87ER-60522)
(DE94-008503; DOE/ER-60522/7) Avail: CASI HC A03/MF A01

This progress report summarizes results, as of August 1993, for DOE grant DE-FG-02-76ER60522 during the fiscal period 1/1/93 to 12/31/93, which is the first year of a 3-year grant cycle. The overall goals of the grant are to develop advanced x-ray detector technologies, especially as applicable for biological and materials research at the national laboratories, and to train graduate and post-doctoral students on the use of these technologies via the performance of original biological and materials research. As summarized below, there has been good progress toward achieving the research goals of the original 3-year proposal; in consequence, the research plan and the total budget for the rest of 1993 and beyond is still well described by the original proposal. Accomplishments since the last progress report include: (1) A 1k x 1k fiber optically coupled CCD detector was assembled, tested at CHESS and is slated for extended user trials this Fall. A 2k x 2k CCD detector is being assembled for permanent installation at CHESS. (2) X-ray detector phosphors, calibration techniques, and system software have been developed. (3) The design of a Pixel Array Detector, a collaborative project with the Advanced Photon Source, has been initiated. (4) The properties of biomembrane lipids under extremes of pressure have been investigated. High pressure instrumentation and techniques have been developed. (5) The physics of mesophase formation in biomembrane lipid, surfactant, and polymeric systems have been studied. This includes study of the interaction of membrane proteins with elastically strained lipid bilayers. (6) Work has been initiated on the use of thermal diffuse scatter from proteins as a probe of protein dynamics. (7) Studies on luminescent phenomena have been reported. Since the last progress report (dated 15 May 1992), this work has resulted in 10 published papers, 7 abstracts, 1 Ph.D. thesis and 1 technical report. DOE

THE ORGANIZATION OF THE SUPRACHIASMATIC CIRCADIAN PACEMAKER OF THE RAT AND ITS REGULATION BY NEUROTRANSMITTERS AND MODULATORS Final Technical Report, 1 Apr. 1990 - 30 Sep. 1993
Martha U. Gillette, Dong Chen, Steven Demarco, Jian Ding, and Lia Faiman 2 Feb. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0205-90)
(AD-A277324; AFOSR-94-0047TR) Avail: CASI HC A04

Our research addresses the cellular organization and regulation of a biological clock that controls daily (circadian) rhythms of behavior (e.g., performance), physiology and metabolism in mammals. This clock, located in the brain's suprachiasmatic nucleus (SCN), can be removed in a slice of hypothalamus, maintained in a life support system for up to 3 days and studied directly. Using this approach, progress in the 3 1/2 years of this award has been made in: (1) localizing time-keeping properties within the SCN of rat, (2) identifying electrophysiological properties of neurons in the major SCN subdivisions, (3) establishing regulatory roles for serotonin, a neuromodulatory input from the brain's arousal center in the raphe nuclei, as well as for neuropeptide Y, an input from the intergeniculate area, (4) determining the level of glutamic acid decarboxylase (GAD), the biosynthetic enzyme for the inhibitory neurotransmitter GABA, in SCN over the circadian cycle, and (5) examining the involvement of glutamate/nitric oxide signal transduction in mediating light entrainment of the SCN through retinal inputs.

This project involves both individual and interactive research projects at the University of Illinois and the USAF School of Aerospace Medicine.

NINTH INTERNATIONAL WORKSHOP ON PLANT MEMBRANE BIOLOGY
1993 285 p Workshop held in Monterey, CA, 19-24 Jul. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG03-92ER-20081)
(DE94-005690; CONF-9207229) Avail: CASI HC A13

This report is a compilation of abstracts from papers which were discussed at a workshop on plant membrane biology. Topics include: plasma membrane ATP-ases; plant-environment interactions, membrane receptors; signal transduction; ion channel physiology; biophysics and molecular biology; vaculor H+ pumps; sugar carriers; membrane transport; and cellular structure and function. THE MAGNESIUM CHELATION STEP IN CHLOROPHYLL BIOSYNTHESIS
J. Weinstein Feb. 1994 19 p
(Contract DE-FG09-89ER-13989)
(DE94-008727; DOE/ER-13989/4) Avail: CASI HC A03/MF A01

Mg-chelatase catalysis is the first step unique to chlorophyll synthesis, namely the insertion of magnesium into protoporphyrin IX. When pea (Pisum sativum L., cv. Spring) chloroplasts are lyzed in a buffer lacking magnesium and the thylakoids removed by centrifugation, the remaining mixture of light membranes and soluble proteins (LM/S) has high Mg-chelatase activity. Several lines of evidence are presented to show that the magnesium insertion catalyzed by this preparation is a two-step reaction consisting of activation followed by magnesium chelation. An activated state of Mg-chelatase is achieved by preincubating LM/S with ATP. The activated state is observed as the elimination of the approximately 6 min lag in the rate of magnesium chelation upon addition of the prophyrin substrate. The activity of LM/S assayed at low protein concentrations can be greatly enhanced by preincubating at high protein concentrations (12 mg/ml is optimal). This activation effect requires the presence of both LM and S fractions, as well as ATP. Both steps require ATP, but at different concentrations; the first step is optimal at greater than 0.5 mM (EC(sub 50) = 0.3 mM) and the second step is optimal at 0.3 mM (EC(sub 50) less than 0.2 mM). ATP in the first step could be replaced by ATP(gamma)S; this analog could not sustain activity in the second step. This activated state was stable for at least 30 min at room temperature, but chilling of preincubated LM/S on ice for 30 min caused an almost complete loss of the activated state. DOE

LIGHT UTILIZATION AND PHOTOINHIBITION OF PHOTOSYNTHESIS IN MARINE PHYTOPLANKTON
P. G. Falkowski, R. Greene, and Z. Kolber 1993 49 p Presented at the 41st Harden Conference on Photoinhibition of Photosynthesis, London, England, 5-10 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE94-005505; BNL-49821; CONF-9309312-1) Avail: CASI HC A03/MF A01

Based on the record of the oldest identifiable fossils, the first oxygenic photosynthetic organisms appeared about 2 x 10(exp 9) years ago in the form of marine single celled, planktonic procaryotes. In the intervening eons, phytoplankton have evolved and diversified; presently they represent at least 11 classes of procaryotic and euacaryotic photoautotrophs. While the carbon of these organisms cumulatively amounts to only 1 to 2% of the global plant biomass, they fix between 35 and 50 gigatonnes (x 10(exp 9) metric tons) of carbon annually, about 40% of the global total. On average, each gram of phytoplankton chlorophyll converts about 6% of the photosynthetically active radiation (440 to 700 nm) incident on the sea surface to photochemical energy. Despite a great deal of variability in ocean environments, this photosynthetic conversion efficiency is relatively constant for integrated water column production. Here we review the factors determining light utilization efficiency of phytoplankton in the oceans and the physiological acclimations which have evolved to optimize light utilization efficiency. DOE

CHARACTERIZATION AND UTILIZATION OF OPIATE-LIKE HIBERNATION FACTORS Report, 15 Jul. 1992 - 15 Dec. 1993
Peter R. Oeltgen 8 Dec. 1993 69 p
(Contract DAMD17-92-C-2026; DA Proj. 3M1-62787-A-874)
(AD-A278136) Avail: CASI HC A04/MF A01

A hibernation induction trigger (HIT) molecule derived from the plasma of deeply hibernating woodchucks exerts profound effects mimicking a hibernation-like state when infused I.C.V. or I.V. in primates. The profound opiate-like behavioral and physiological depression occurring shortly after the infusion of the HIT-containing albumin fraction include hypothermia, bradycardia, long-term hypophagia and markedly depressed renal function. All of the aforementioned effects are reversed or retarded by the infusion of the opiate antagonists, naloxone and naltrexone. Such evidence enforces our hypothesis that the HIT molecule is not specific for hibernators, but that it may initiate its action through specific opioid receptor(s). We have shown that only DADLE, a delta class of opiate, could induce hibernation in summer-active ground squirrels (the traditional bioassay) in a fashion similar to those injected with HIT. Such evidence indicates that this delta opioid mimics the action of the HIT molecule and may be intimately involved in natural winter and summer-induced hibernation. Recently, we have developed a rapid in vitro bioassay utilizing the criteria of DNA and protein synthesis inhibition to monitor the metabolic inhibitory activity of hibernating plasma, and plasma fractions as well as the metabolic effects of the delta opioids DADLE and D-Pen 2.5-Enkephalin (DPDPE). FUTURE DIRECTIONS OF NONLINEAR DYNAMICS IN PHYSICAL AND BIOLOGICAL SYSTEMS. (PHYSICA D NONLINEAR, VOLUME 68, NUMBER 1)
P. L. Christiansen, J. C. Eilbeck, and R. D. Parmentier 15 Sep. 1993 196 p Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(Contract DAJA45-92-M-0163)
(AD-A278085; R/D-6891-MA-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Early in 1990 a scientific committee was formed for the purpose of organizing a high-level scientific meeting on future directions of nonlinear dynamics in physical and biological systems, in honor of Alwyn Scott's 60th birthday (December 25, 1991). As preparations for the meeting proceeded, they were met with an unusually broad-scale and high level of enthusiasm on the part of the international nonlinear science community, resulting in a participation by 168 scientists from 23 different countries in the conference, which was held July 23 to August 1 1992. The contributions to this present volume have been grouped into the following chapters: solitons, superconducting devices, biomolecular dynamics, nonlinear optics, and classical and quantum mechanical lattice dynamics. INTERACTIVE RECONSTRUCTION OF ANATOMICAL STRUCTURES WITH FREE-FORM SURFACES Ph.D. Thesis [RECONSTRUCTION INTERACTIVE D'ELEMENTS ANATOMIQUES A L'AIDE DE SURFACES DE FORME LIBRE]
Rene Ebel 1993 318 p In FRENCH
(ISSN 0751-1353)
(TELECOM-93-E-002; ETN-94-95980) Avail: CASI HC A14/MF A03

An approach to the mathematical description of the surface of a three dimensional (3D) reconstruction of an anatomical structure from a set of 3D data point samples is described. The approach could be compared to CAGD (Computer Aided Geometric Design) insofar as it is based on interactivity and on the use of free form patches to describe the surfaces. The advantage of this approach lies in the quality of the surfaces obtained

(G(sup 1) continuity or tangent plane continuity is satisfied) and in the possibility of performing reconstructions from arbitrary sets of 3D points. It is assumed that the elements to be reconstructed are smooth and that they are simple enough to enable interactivity. Reconstruction of treelike structures such as blood vessels are addressed, distinguishing three constituent elements: tubular parts, 'caps,' and 'junctions'. For each one, a particular method of reconstruction is developed. The modeling of a tubular element begins with an interactive step of estimation of axial positions. The next steps consist of automatically fitting a right generalized cylinder on the data by an iterative optimization technique. The resulting surface is composed of B spline patches. Elements like 'caps' and 'junctions' are created automatically, by the prolongation of the tubular surface with Bezier-Gregory patches. The reconstruction method proposed for tubular surfaces is extended to organs with more general forms. This time, the user is requested to associate a predefined polyhedral structure with the data. After this interactive operation, the computer produces automatically a surfacic approximation of the data by means of triangular and rectangular Bezier-Gregory patches joined with G(sup 1) continuity. HYDROGENATED AMORPHOUS SILICON (a-Si:H) BASED GAMMA CAMERA: MONTE CARLO SIMULATIONS
H. Lee, J. S. Drewery, W. S. Hong, T. Jing, S. N. Kaplan, A. Mireshghi, and V. Perez-Mendez Jan. 1994 12 p Presented at the SPIE Medical Imaging Conference, Newport Beach, CA, 13-18 Feb. 1994
(Contract DE-AC03-76SF-00098)
(DE94-007042; LBL-35050; CONF-940254-1) Avail: CASI HC A03/MF A01

A new gamma camera using a-Si:H photodetectors has been designed for the imaging of heart and other small organs. In this new design, the photomultiplier tubes and the position sensing circuitry are replaced by 2-D array of a-Si:H p-i-n pixel photodetectors and readout circuitry which are built on a substrate. Without the photomultiplier tubes this camera is light weight, hence, it can be made portable. To predict the characteristics and the performance of this new gamma camera, we did Monte Carlo simulations. In the simulations, 128 x 128 imaging array of various pixel sizes were used. Tc-99m (140keV) and Tl-201) (70keV) were used as radiation sources. From the simulations, we could obtain the resolution of the camera and the overall system, and the blurring effects due to scattering in the phantom. Using the Wiener filter for image processing, restoration of the blurred image could be achieved. Simulation results of a-Si:H based gamma camera were compared with those of a conventional gamma camera. DOE

PERSPECTIVES OF GLUCOSE SENSING BASED ON A CHARGE-MODULATING COMPETITION REACTION Ph.D. Thesis
Jans Kruise 1993 164 p Sponsored by Ministry of Economic Affairs
(ISBN-9-09-005754-4; ETN-94-96030) Avail: CASI HC A08/MF A02

Diabetes mellitus is introduced, existing detection principles for glucose sensors are reviewed, and a method based on a charge modulating competition reaction for measurement of glucose dependent concentration of either oxygen, hydrogen peroxide or gluconic acid, as opposed to an enzyme based glucose sensor, is proposed. The detection principal, based on a competition reaction between glucose and a charged glucose derivative, is described. Both species can bind to receptor molecules present in a porous membrane. Due to the competition reaction, the concentration of bound charged glucose derivative depends on the glucose concentration in the sample solution. The aim is to find a method to detect this glucose dependent concentration of bound charged groups in the receptor membrane. The development of a Donnan potential across the membrane solution interface is modeled. Optimal system parameters, which lead to a maximum sensitivity of the Donnan potential towards changes in glucose concentration, are derived. The feasibility of static potentiometric detection of a Donnan potential with an ISFET based device is discussed. ISFET based membrane conductivity and miniature conductivity sensor are described. Measurement results of membranes in which the bound charge (of charged glucose derivatives) can be modulated by glucose are given. The membranes were characterized using the so called ion step method. This method was also used to prove the operation of the competition reaction between glucose and the charged glucose derivative. The effect of changes in glucose concentration on the membrane conductivity was investigated. ESA

PROCEEDINGS OF THE DCIEM DIVER THERMAL PROTECTION WORKSHOP
R. Y. Nishi, ed. Jan. 1992 218 p Workshop held in North York, Ontario, 31 Jan. - 2 Feb. 1989
(DCIEM-92-10; DSIS-92-03143; CTN-94-61181) Avail: Issuing Activity
(Defence and Civil Inst. of Environmental Medicine, 1133 Sheppard Ave. W., P.O. Box 2000, North York, ON M3M 3B9 Canada)

As a result of a renewed interest in diver thermal protection, a workshop was organized under the auspices of the America, Britain, Canada, and Australia Information Exchange Program on Naval Diving in order to bring together representatives from all the components associated with military diving. Papers were presented at the workshop on active and passive diver thermal protection, medical implications of diving in cold water, diving suit buoyancy characteristics, thermal insulation materials, diving suit undergarments, hot-water heating and electrical heating of diving suits, improvement of cold tolerance in humans, thermoregulation, diver monitoring systems, and test facilities. Separate abstracts have been prepared for four papers from this workshop. For individual titles, see N94-31739 through N94-31742.

THERMOTROPIC LIQUID CRYSTALS: A VARIABLE Clo MATERIAL
c54
Rand R. Biggers *In* Defence and Civil Inst. of Environmental Medicine, Proceedings of the DCIEM Diver Thermal Protection Workshop Jan. 1992 p 33-39 (For primary document see N94-31738 09-52)
Avail: Issuing Activity (Defence and Civil Inst. of Environmental Medicine, 1133 Sheppard Ave. W., P.O. Box 2000, North York, ON M3M 3B9 Canada)

Thermotropic liquid crystals comprise a class of mesophase materials with variable heat transfer characteristics. Utilization of their unique thermal transport properties in a diving garment would add an additional dimension of flexibility to diver thermal protection. The response of the effective thermal conductivity of liquid crystals to applied fields is sufficiently strong that an excellent opportunity exists to exploit the heat transfer characteristics of these materials to produce variable-Clo garments. The effects of alternating current fields on the thermal transfer rate in N-(p-methoxy benzylidene)-p- butylaniline (MBBA) were studied. The results suggest that the best utilization of liquid crystals would be in a cooling mode. The minimum thermal conductivity of MBBA gives it a Clo value roughly one half that of an equivalent thickness of neoprene. It is expected that when more liquid crystals are accurately measured, they might approach the Clo values of thinsulate. Recent experiments have suggested that inclusion of liquid crystal cells in a thinsulate undergarment would provide a cooling ability while retaining about 95 percent of the garment's insulating ability. A composite thinsulate and liquid crystal undergarment could provide nine hours of protection against hypothermia, compared to three hours with the conventional garment. Author (CISTI)

REVIEW OF PHARMACOLOGICAL APPROACH TO IMPROVE COLD TOLERANCE
A. L. Vallerand and I. Jacobs *In its* Proceedings of the DCIEM Diver Thermal Protection Workshop Jan. 1992 p 119-123 (For primary document see N94-31738 09-52)
Avail: Issuing Activity (Defence and Civil Inst. of Environmental Medicine, 1133 Sheppard Ave. W., P.O. Box 2000, North York, ON M3M 3B9 Canada)

It has been shown that beta-adrenergic drugs increase heat protection in humans exposed to comfortable ambient temperatures. The influence of a mixture of ephedrine and caffeine on cold tolerance was investigated in male subjects during 3-hour exposures to 10 C air. The drug ingestion reduced the total drop in core, mean skin, and mean body temperatures, thus producing significantly warmer final core, mean skin, and mean body temperatures compared to placebo ingestion. The drug ingestion increased the total 3-hour energy expenditure by 18.6 percent compared to that of the placebo ingestion in the cold. Using the non-protein respiratory exchange ratio to calculate the rates of substrate oxidation, it was found that the drug ingestion increased carbohydrate oxidation by 41.7 percent above that of the placebo, but did not alter lipid or protein metabolism. The results demonstrate that the ingestion of a mixture of ephedrine and caffeine improves cold tolerance in man by significantly increasing body temperatures in the cold. These improvements were caused by a greater energy expenditure, which appears to be dependent on an enhanced carbohydrate utilization. Author (CISTI)

LIPID METABOLISM IN COLD-EXPOSED HUMANS
A. L. Vallerand and I. Jacobs *In its* Proceedings of the DCIEM Diver Thermal Protection Workshop Jan. 1992 p 139-142 (For primary document see N94-31738 09-52)
Avail: Issuing Activity (Defence and Civil Inst. of Environmental Medicine, 1133 Sheppard Ave. W., P.O. Box 2000, North York, ON M3M 3B9 Canada)

Changes in lipid utilization associated with cold exposure in humans was investigated along with the role of plasma triglyceride (TG) and lipolysis in lipid metabolism during cold exposure. Male subjects were subjected to an intravenous fat tolerance test (an index of plasma TG utilization) at thermal neutrality, in 10 C cold, and in the cold 24 hours after the first cold test. Rates of substrate oxidation were calculated from indirect calorimetry, and changes in plasma glycerol levels were measured as an index of lipolysis. Cold exposure reduced mean body temperature by 3.2 C and increased energy expenditure 2.6 times compared to warm values. Cold exposure also increased fat oxidation by 71 percent and plasma glycerol levels, but did not alter removal rates of the infused plasma TG. The second cold test was accompanied by a further increase in fat utilization and plasma glycerol levels, with unchanged fat tolerance. The results show that cold exposure in humans significantly increases the oxidation of lipid, and that plasma TG does not appear to be an important energy substrate in the cold. It is suggested that white adipose tissue and possibly intramuscular TG, not plasma TG, are the preferred sources of fatty acids for oxidation in cold-exposed humans. Author (CISTI)

ERRORS ASSOCIATED WITH THE USE OF HEAT FLOW TRANSDUCERS
M. B. Ducharme and J. Frim *In* Defence and Civil Inst. of Environmental Medicine, Proceedings of the DCIEM Diver Thermal Protection Workshop Jan. 1992 p 213-221 (For primary document see N94-31738 09-52)
Avail: Issuing Activity (Defence and Civil Inst. of Environmental Medicine, 1133 Sheppard Ave. W., P.O. Box 2000, North York, ON M3M 3B9 Canada)

Direct assessment of heat flux from the body is a basic measurement in thermal physiology. Heat flux transducers (HFTs) are increasingly being used for that purpose, but questions have been raised about the accuracy of the manufacturer's constant of calibration and the effect of the thermal resistance of the HFT on the true thermal flux from the skin. Two different types of waterproofed HFTs were checked for their calibration using the Rapid-K heat flow meter conductivity instrument. The mean difference between the recalibrations and the manufacturer's constants was +20.2 = or - 7.1 percent for Thermonetics HFTs and -0.7 = or - 4.8 percent for Concept Engineering HFTs. The significant difference in the calibration error between the two manufacturers becomes an important criterion for selecting HFTs. A model capable of simulating a large range of insulation values was used to study the effect of the underlying tissue insulation on the relative error in thermal flux due to the HFT thermal resistance. The data show that the deviation from the true value increases with the reciprocal of the underlying tissue insulation. The underestimation of heat flux through the skin measured by an HFT is minimum when the HFT is used on vasoconstricted skin in cool subjects, but becomes important when used on warm vasodilated subjects. MUSCLE DISUSE THROUGH TAIL-SUSPENSION: ETIOLOGY AND THERAPEUTICS Ph.D. Thesis
Ellis Calvin Gayles 1993 110 p
Avail: Univ. Microfilms Order No. DA9320424

Humans and animals experience a loss of muscle mass and size during exposure to the weightless environment of space. This effect is seen predominantly in the postural muscles of the leg. In order to more extensively study these effects, ground based models have been developed to mimic the effects of space flight on the mammalian musculoskeletal system. For rats or mice, the most common model involves suspending the animal by its tail such that the hind limbs are unloaded and the animal is tilted 30 degrees head down. The animal may only use its forelimbs for locomotion. In addition to unloading of the hind limbs, other physiological effects of suspension include anorexia, diuresis, and stress. The present research investigated the etiology of these suspension effects on mouse muscle mass and protein. Additionally, the sex and genotype dependence of these effects was also investigated. Two different therapeutic treatments were also developed to ameliorate the effects of suspension on the muscles. The results of the present studies estimate that unloading is responsible for approximately 50 percent of the suspension effect on muscle. Anorexia and stress are estimated to account for the other 50 percent. The effect of suspension on muscle mass was independent of sex or genotype; however the effect of suspension on muscle protein did demonstrate a genotype dependence. A resistance exercise regimen was developed to reduce the effects of suspension on the muscles. Suspended mice were required to walk on a grid with weight attached to their tails. This exercise regimen was performed daily during the suspension period. The daily exercise did not reduce the loss of muscle mass or muscle protein in the exercised

mice. Pulsed electromagnetic fields (PEMF's) were also investigated as a method of muscle stimulation to reduce the effects of suspension. These fields had a positive effect on muscle mass and protein content. Suspended mice exposed to the PEMF's maintained more muscle mass than normal suspended mice. Additionally, mice exposed to the PEMF's averaged more muscle protein than non-field mice. These results suggest that PEMF's may provide an efficacious method for the alleviation of suspension effects on muscle. Dissert. Abstr.

ISOLATING STRAIN PARAMETERS CORRELATED TO SKELETAL ADAPTATION Ph.D. Thesis
Ted S. Gross 1993 176 p
Avail: Univ. Microfilms Order No. DA9328176

The close association between skeletal morphology and parameters such as strain magnitude, strain rate, and strain energy density suggest that the cellular populations of bone perceive and respond to mechanically induced deformations within the tissue. However, the specific stimulus responsible for the control and maintenance of skeletal tissue has yet to be defined. In this study, we develop an in vivo model of skeletal adaptation, assess whether physical stimuli are necessary to maintain bone mass in the adult skeleton, isolate mechanical parameters correlated to sites of adaptation induced by an exogenous loading regimen, and lastly validate these relationships by their ability to predict adaptation in the same model under alternate loading conditions. The right radii of three groups of five adult male turkeys were functionally isolated via parallel metaphyseal osteotomies. The left radius served as an intact, contra-lateral control. The first group of animals remained unloaded for a period of eight weeks. The remaining two groups were exposed to a four week exogenous loading regimen placing the bone primarily in bending. The groups were identical except for the orientation of the transcutaneous loading pins, which were rotated 90 degrees in the transverse plane in the last group of animals (group 'B'). Using multiple step-backward regression, adaptive responses were related to candidate mechanical parameters defined by orthotropic finite element models whose geometry was based upon each animal's intact control radius. Eight weeks of disuse induced a mean (+/- S.D.) 12.1 +/- 7.1 percent reduction of bone mass. The loss was achieved primarily via uniform endosteal expansion suggesting that the entire cortex is sensitive to mechanical stimuli. The exogenous loading regimen induced a 20.4 +/- 28.8 percent increase in bone area in group 'A', and a 35.2 +/- 32.8 percent increase in group 'B', primarily via periosteal expansion. In both groups, the location of greatest periosteal expansion corresponded with sites of minimum rather than maximum strain magnitudes. Of the many candidate correlates, only the surface epsilon(sub zz) gradient in the circumferential direction was validated by its ability to predict adaptation in the alternate loading group. The predictive power of this parameter is particularly intriguing when considering possible physiologic mechanisms of cellular signal transduction such as streaming potentials and cellular communication via gap junctions. Dissert. Abstr.

VALIDATION AND SENSITIVITY ANALYSIS OF TEXAS HUMAN THERMAL MODEL PREDICTIONS DURING COLD WATER IMMERSION Final Report, Mar. - Sep. 1992
Barry S. Shender and Jonathan W. Kaufman 1 Feb. 1993 153 p
(AD-A275240; NAWCADWAR-93069-60) Avail: CASI HC A08/MF A02

The Texas Human Thermal Model has been used to simulate the effects of thermal stresses on individuals under a variety of conditions. AS part of a U.S. Navy effort to develop integrated protection garments, the Model has been modified to predict tolerance to cold water immersion with garments whose CLO values are less than 0.1. Other program modifications have been implemented leading to easier use, enhanced speed and versatility and accuracy of predictions. With these modifications, a validation of Model performance was done using human data obtained from Finnish cold water immersion suit assessments. Limitations in Model performance were found but predictions of rectal temperature (T(sub re)) were in reasonable agreement to actual results. A sensitivity analysis was also performed to determine which Model parameters were most effected by cold water immersions. The condition tested was head-out immersion in 40 deg F water by 160 lb man with a 10 mm mean skinfold thickness. Based on the thermal end points, the Model was sensitive to body segmental changes in CLO (ordered from most to least sensitive): chest and abdomen, leg, head, arm, foot, and hand. Mean skinfold thickness, basal metabolic rate, body weight and level of exercise metabolic rate up to 100 BTU/her were the most important physical parameters affecting Model performance. Lowering the water temperatures to 28 deg F caused a simple shift by in segment temperature predictions with respect to 40 deg F estimates. The overall shapes of the curves at 28 and 40 deg F were essentially the same, though the 28 deg F curves had steeper slopes leading to a faster fall to critical temperatures. DTIC

MODELS OF THE NEURONAL MECHANISMS OF TARGET LOCALIZATION OF THE BARN OWL Final Report, 11 Sep. 1990 - 20 Sep. 1993
John Pearson Nov. 1993 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-89-C-0131)
(AD-A277332; AFOSR-94-0061) Avail: CASI HC A03

Models of the computation of sound direction in the brainstem and midbrain of the barn owl (tyto alba) were developed. Nucleus laminaris is the first site of interaural time-delay (ITD) processing. It was shown that standard neuron models would have to have unrealistically fast time constants in order to match the 10 micro-second ITD resolution characteristic of laminaris neurons. Three physiological reasonable, qualitatively distinct alternatives, were developed. Nucleus ventralis lemnisci lateralis pars posterior (VLVp) and the lateral shell of the central nucleus of the inferior colliculus (ICL) are the first two stages of interaural level differences (ILD) processing. It was shown how a thermometer code of ILD could be formed in VLVp through competitive dynamics, and how the ILD-tuned responses of ICL neurons could derive from the VLVp through lateral inhibition. It was shown how this architecture could be modified to achieve near independence from the average binaural level. Experimentalists are now checking the predictions of these models of ILD and ITD processing. DTIC

NONINVASIVE SPECTROSCOPIC DIAGNOSIS OF SUPERFICIAL OCULAR LESIONS AND CORNEAL INFECTIONS
J. R. Mourant, I. J. Bigio, T. Johnson, T. Shimada, D. C. Gritz, and K. Storey-Held 1994 10 p Presented at the OE/LASE 1994 Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract W-7405-eng-36)
(DE94-006231; LA-UR-94-16; CONF-940142-8) Avail: CASI HC A02/MF A01

The potential of a rapid noninvasive diagnostic system to detect tissue

abnormalities on the surface of the eye has been investigated. The optical scatter signal from lesions and normal areas on the conjunctival sclera of the human eye were measured in vivo. It is possible to distinguish nonpigmented pingueculas from other lesions. The ability of the system to detect malignancies could not be tested because none of the measured and biopsied lesions were malignant. Optical scatter and fluorescence spectra of bacterial and fungal suspensions, and corneal irritations were also collected. Both scattering and fluorescence show potential for diagnosing corneal infections. DOE

NUMERICAL MODEL OF THE THERMAL BEHAVIOR OF AN EXTREMITY IN A COLD ENVIRONMENT INCLUDING COUNTER-CURRENT HEAT EXCHANGE BETWEEN THE BLOOD VESSELS
Avraham Shitzer, Leander A. Stroschein, Paul Vital, Richard R. Gonzales, and Kent B. Pandolf Mar. 1994 122 p
(AD-A278099; USARIEM-T94-10) Avail: CASI HC A06/MF A02

A numerical model of the thermal behavior of an extremity, e.g., finger, is presented. The model includes the effects of: (1) heat conduction, (2) metabolic heat generation, (3) heat transport by blood perfusion, (4) heat exchange between the tissue and the large blood vessels, and (5) arterio-venous heat exchange. Heat exchange with the environment through a layer of thermal insulation, depicted by thermal handwear is also considered. The tissue is subdivided into four concentric layers. The layers described, from the center outward, as core, muscle, fat, and skin. Differential heat balance equations are formulated for the tissue and the major artery and the major vein. These coupled equations are solved numerically by the alternating direction method employing a Thomas algorithm. The numerical scheme was tested extensively for stability and convergence. Results of the convergence tests are presented and discussed and the dependence on the number of grid points is demonstrated. Plots of tissue and blood temperatures along selected nodes of the model are shown for different combinations of parameters. The effect of counter-current heat exchange between the artery and the vein on the thermal balance of the extremity is presented. This shows clearly the conservation of energy achieved due to this mechanism. The report is concluded by considering the effects of cold induced vasodilation on tissue temperature cycling. DTIC

FAST NONSUPERVISED 3D REGISTRATION OF PET AND MR IMAGES OF THE BRAIN
Jean-Francois Mangin (Commissariat a l'Energie Atomique, Orsay, France.), Vincent Frouin (Commissariat a l'Energie Atomique, Orsay, France.), Isabelle Bloch, Bernard Bendriem, and Jaime Lopez-Krahe 1993 46 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0751-1337)
(TELECOM-93-C-006; ETN-94-95979) Avail: CASI HC A03

A fully nonsupervised methodology dedicated to the fast registration of PET (Positron Emission Tomography) and MR (Magnetic Resonance) images of the brain is proposed. Discrete representations of the surfaces of interest (head or brain surface) are automatically extracted form both images. A shape independent surface matching algorithm yields a rigid body transformation, which allows the transfer of information between both modalities. A 3D (three dimensional) extension of the chamfer matching principle makes up the core of this surface matching algorithm. The optimal transformation is inferred from the minimization of a quadrative generalized distance between discrete surfaces, taking into account between modalities differences in the localization of the segmented surfaces. The minimization process is efficiently performed via the precomputation of a 3D distance map. Validation studies using a dedicated brain shaped phantom showed that the maximum registration error was of the order of the PET pixel size (2 mm) for the wide variety of tested configurations. The software is routinely used in a clinical context by physicians (more than 50 registrations performed). The entire registration process requires about five minutes on a conventional workstation. DEVELOPMENT OF A VIDEO FLUORESCENCE SYSTEM FOR ASSESSING BURN DEPTH Final Report, 26 May 1992 - 25 Dec. 1993
John A. Parrish, Norman S. Nishioka, Maya Jerath, Dominic Bua, and Geoffrey Silver 14 Jan. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAMD17-92-J-2019; DA Proj. 3M2-63004-D-805)
(AD-A278127) Avail: CASI HC A03

The ultimate objective of our research is to develop an integrated laser-based system for treating burn injury. The first phase of this development effort was funded under the present contract. The objective was to design, construct and optimize a diagnostic system suitable for clinical use in humans that accurately determines burn depth. The diagnostic system utilizes an exogenously administered fluorescent dye to label skin vasculature that is detected by a fluorescence imaging system. During the past year the design criteria for such a system were formulated, the components acquired and the system constructed. A series of experiments have been carried out in animals to test and optimize the system. We have demonstrated that the ratio of fluorescence intensity detected by the system at a burn site to that detected from normal skin, can be used to accurately determine the extent of burn injury. The burn diagnostic system is now ready for clinical deployment to gather further data and refine the system. DTIC

MEDICAL PROBLEMS IN HIGH MOUNTAIN ENVIRONMENTS. A HANDBOOK FOR MEDICAL OFFICERS Final Report
Allen Cymerman and Paul B. Rock Feb. 1994 64 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A278095; USARIEM-TN94-2) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This Technical Note describes the physiological and medical basis for the prevention and treatment of altitude-related illnesses and a description of the reduced mental and physical performance incurred by troops in an operational high terrestrial altitude environment. Medical officers are provided with background information for the diagnosis, prevention, and management of the primary altitude-induced medical problems: acute mountain sickness (AMS), high altitude pulmonary edema (HAPE), and high altitude cerebral edema (HACE). Secondary medical problems are also reviewed as are precautionary and contributory sea-level medical conditions and general physiological and psychological factors affecting the performance of soldiers at altitude. SITUATIONAL AWARENESS: A FEASIBILITY INVESTIGATION OF NEAR-THRESHOLD SKILLS DEVELOPMENT Final Report, 27 Jul. 1987 - 31 May 1991
Grant E. Secrist and Bryce O. Hartman Jan. 1994 75 p
(Contract F33615-87-C-0614)
(AD-A276467; AL/AO-TR-1994-0002) Avail: CASI HC A04/MF A01

A decisive capability possessed by superior fighter-attack pilots is

keen situational awareness. In this report, we examine the trainability of near-threshold information acquisition and processing skills that appear to be vital to heightened situational awareness. The investigation served two purposes: (1) determine the effects or near-threshold training on target detection, recognition, and identification performance; and (2) assess the general transfer of this training to velocity discrimination and peripheral vision two-flash threshold performance. Ten flight-qualified AFROTC cadets served as trainees. Each trainee received 5,040 near-threshold training trials over five consecutive days. The findings indicate that near-threshold skills are trainable. Group and individual learning curves reflected consistent improvement in target detection, recognition, and identification accuracy at target durations down to 33 ms. Statistically significant differences were found between group baseline and post-training performance. DTIC

TOWARDS SIMPLICITY: NOISE AND COOPERATION IN THE PERFECT INTEGRATOR Professional Paper
A. R. Bulsara Feb. 1994 19 p
(AD-A276256) Avail: CASI HC A03/MF A01

Neuroscientists have known for decades that sensory information is encoded in the intervals between the action potentials or spikes characterizing neural firing events. Statistical analyses of experimentally obtained spike trains have shown the existence of a significant random component in the inter-spike intervals. There has been speculation, of late, that the noise may actually facilitate the transmission of sensory information; certainly there exists evidence that noise in networks of neurons can dynamically alter the properties of the membrane potential and the time constants. This paper describes the recent rekindling of interest in the Stochastic Resonance phenomenon leading to speculation that such nonlinear cooperative effects may occur naturally in living systems. MODEL-BASED SCIENTIFIC DISCOVERY: A STUDY IN SPACE BIOENGINEERING Ph.D. Thesis
Nicolas Groleau 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

This thesis describes a novel system that modifies the theory contained in a model of the normal human orientation system. This system, called MARIKA, demonstrates automated scientific discovery in an actual scientific domain through techniques adapted from diagnosis and design. MARIKA comprises a simulation module, a constraint propagation module and a model revision module. The module is captured in a simulation environment that produces time-varying signals. The model parameters are represented as constrained range variables and the input, output and intermediary signals are segmented in time and approximated by linear combinations of a set of four simple shape adequate for the vestibular domain. The model linear differential equations and boundary conditions are transformed into constraints on the curve fit parameters and the model parameters. Some extensions are also provided to cover simple non-linear cases and steady state conditions. Clinical data are abstracted using the shapes predicted by the model. These data are then compared to simulation predictions by propagating the constraints relating the model and the curve fit parameters. In case of contradiction, the model is modified by either extending the range of model parameters to pathological values or altering the structure of the model according to pre-indexed methods. MARIKA correctly models normal vestibular data and several end organ and nervous processing defects. MARIKA demonstrates the synergy of diagnosis and design techniques, qualitative and quantitative representation, and modeling, simulation, and artificial intelligence for a routine form of automated scientific discovery. MARIKA's set of shapes could readily be enhanced to be used to perform model-based theory refinement on a variety of linear domains. These encouraging results could lead to a useful clinical vestibular tool and to a space vestibular adaptation scientific discovery system.

ANALYSIS OF PURSUIT TRACKING EYE MOVEMENTS IN PILOTS AND NONFLIERS Final Report, 1 Jan. 1993 - 1 Jan. 1994
Edward J. Engelken, Kennith W. Stevens, Ann F. Bell, and Jack D. Enderle 1 Jan. 1994 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. ILIR; AF Proj. 7755)
(AD-A276597; AL/AO-PC-1994-0003) Avail: CASI HC A02

Pursuit tracking eye movements were recorded and analyzed from a group of Air Force pilots and a group of nonflying Air Force Members. The tracking performance of the pilots was compared to the performance of the nonfliers. Subjects tracked a small spot of light moving sinusoidally in the horizontal plane at frequencies ranging from 0.2 to 1.0 Hz while their eye movements were recorded. An adaptive nonlinear digital filter was used to separate the total tracking response (TTR) into smooth pursuit (SP) and saccadic (SA) components. There were no significant differences in tracking performance between pilots and nonfliers. DTIC

(AD-A277379; AFOSR-94-0127TR) Avail: CASI HC A03

We have completed the final construction of the sound-deaden listening room and the digital library of stored words, numbers, and letters, from nine English speaking males. We conducted pilot experiments on 20 subjects listening to one and two sound sources at a time. The results of the pilot experiments indicated that the sound room was well calibrated and allowed us to determine that a few of the words, letters, and numbers should be recorded. In addition the pilot experiment suggested a few modifications to our protocol. The new utterances have been recorded, the protocol modifications made, and a new set of 10 subjects were tested. The results from this additional set indicated that we had a good listening room, set of utterances, and procedure. From October until January of 1993 we will test the headphone listening protocol making adjustments where necessary. We plan to collect data in the full experiment starting late January 1994.

EFFECTS OF METHAMPHETAMINE AND FATIGUE ON LONG- AND SHORT-TERM MEMORY Interim Report, 1993
R. R. Stanny, A. H. McCardie, and D. F. Neri Nov. 1993 27 p
(AD-A276452; NAMRL-1387) Avail: CASI HC A03/MF A01

We examined the effects of a 10 mg/70 kg oral dose of d-methamphetamine HCl on fatigue-related deficits of short- and long-term memory. We used a recognition memory-search task with two memory loads. In one experimental condition, stimuli were committed to long-term memory (LTM) and performance was rendered automatic by extensive practice with consistently mapped stimuli and responses. In a second condition, the task was organized so that recognition depended on short-term memory (STM) despite equally extensive practice. After 7680 training trials, 13 subjects performed the task at 90-min intervals in a 13.5-h, sustained-performance session that began at 1930 and ended at 0900. At 0116, seven subjects were administered capsules containing 10 mg/70-kg body weight d-methamphetamine HCl, double-blind. The remaining subjects were administered a placebo. Memory-trace strengths and decision speeds declined during the early part of the night in all experimental conditions. The methamphetamine treatment reversed these effects within approximately 2 h of administration. The methamphetamine treatment also reversed an increasing trend in lapse probabilities. The stimulant did not merely produce

criterion shifts that led subjects to respond impulsively (more rapidly but less accurately). These results suggest that the methamphetamine treatment produced genuine increases in accuracy of recognition and that any criterion shifts that may have occurred were more than compensated for by increased accuracy. SENSORY SENSITIVITIES AND DISCRIMINATIONS AND THEIR ROLES IN AVIATION Final Report, 1 Nov. 1990 - 31 Oct. 1993
David M. Regan 30 Nov. 1993 137 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0080-91)
(AD-A277312; AFOSR-94-0078TR) Avail: CASI HC A07

Evidence that intersubject differences in the ability to process motion-defined (MD) shape are not predicted by the ability to process luminance-defined (LD) shape, that motion is processed by hierarchical manner, that discrimination and detection can be dissociated for MD form, and that spatial discrimination for MD and LD form are not entirely mediated by the same mechanism is as follows. Reducing presentation duration or dot lifetime from 1.0 to 0.1 sec progressively reduced the visibility of a MD bar, but did not reduce orientation discrimination for the bar when visibility was held constant. Detection and/or recognition of MD letters can be degraded by removal of brain tissue underlying prestriate cortex without affecting contrast sensitivity, Snellen acuity, low contrast acuity, or sensitivity to motion. Shape discrimination for an MD rectangle can be as low as 2 to 3 percent, as good as for an LD rectangle. Evidence is reported for a neural mechanism sensitive to shape independently of size. Evidence is reported for a neural mechanism directly sensitive to time to collision with an approaching object. A method is reported for measuring intersubject differences in discrimination of time to contact. A titration method for uncovering the color-defined form system is reported. The 40 Hz human brain response indexes magnocellular activity. By recording the magnetic field of the brain, an audio-visual integration area in the brain has been identified. Responses to texture-defined form and color-defined form have been unconfounded from responses to luminance-defined form. A technique for measuring intersubject differences in susceptibility to glare has been developed and is being used in a prospective study of flying safety. Also, the test quantifies visual status in cataract patients. DTIC

Probabilistic learning strategies currently use are inefficient, requiring high classifier complexity and large training samples. In this report, we introduce and analyze an asymptotically efficient differential learning strategy. It guarantees the best generalization allowed by the chosen classifier paradigm. Differential learning also requires the classifier with minimal complexity. The theory is demonstrated in several real-world machine learning/pattern recognition tasks. DTIC

(Contract F49620-92-J-0114)
(AD-A277400; AFOSR-94-0115TR) Avail: CASI HC A03

Psychophysical and theoretical research was conducted on the processes underlying the encoding of relative spatial locations of objects and edges of single objects. Work was done on developing a model of shape representation, called Object Representation by Cores, that is based on previous findings, sponsored by this grant, that the area over which position information is gathered scales with the distance being judged. Experimental work included measuring orientation discrimination thresholds for cone stimuli of various widths and measuring bisection thresholds for stimuli with sinusoidally modulated edges, where both edge modulation frequency and object width were manipulated. Results of both studies verified the key assumption of the model: the scale of the boundariness detector that contributes to perception of object shape covaries with object width. Studies continued on the perception of area. A new line of research was begun on the nature of information observers have about scenes containing multiple objects. DTIC
